Department of Health and Aged Care

Australian Influenza Surveillance Report

Communicable Disease Epidemiology and Surveillance Section (CDESS)

Report no. 07, 2023

Reporting fortnight: Monday 26 June 2023 to Sunday 9 July 2023.

Reporting weeks: 26 and 27, of 2023.

The Department of Health and Aged Care acknowledges the providers of the many sources of data used in this report and greatly appreciates their contribution.

Key Messages

It is important to note that due to the COVID-19 epidemic in Australia, data reported from the various influenza surveillance systems may not represent an accurate reflection of influenza activity. Results should be interpreted with caution, especially where comparisons are made to previous influenza seasons. Interpretation of influenza data from April 2020 onwards should take into account, but are not limited to, the impact of social distancing measures, likely changes in health seeking behaviour of the community including access to alternative streams of acute respiratory infection specific health services, and focussed testing for COVID-19 response activities. For information on COVID-19 incidence, severity, and distribution in Australia, please refer to the [COVID-19 epidemiology reports](#).

Note: This fortnightly report does not contain data from the HealthDirect surveillance system due to data transmission issues. Data will be included in future reports once available.

Activity:

- Influenza-like-illness (ILI) activity in the community reported to FluTracking and ILI presentations to ASPREN sentinel general practitioners (GPs) have been stable in the last fortnight.
- In the year-to-date (1 January to 9 July 2023), there have been 149,989 notifications reported to the National Notifiable Diseases Surveillance System (NNDSS) in Australia, of which 32,132 notifications had a diagnosis date this fortnight.

Severity:

- There is currently not enough information to comprehensively assess the potential severity of the 2023 influenza season at this time.
- In the year-to-date, of the 149,989 notifications of laboratory-confirmed influenza, 134 influenza-associated deaths have been notified to the NNDSS.
- Since seasonal surveillance commenced in April 2023, there have been 1,568 sentinel hospital admissions with influenza, of which 104 (6.6%) were admitted directly to ICU.

Impact:

- This fortnight, community ILI activity has stabilised, notifications of laboratory-confirmed influenza to the NNDSS have stabilised, and admissions to sentinel hospitals with influenza appear to be decreasing.
- It is likely that the impact on society due to the 2023 influenza season this fortnight remains stable.

At-risk populations:

- In the year-to-date, notification rates have been highest in people aged 05–09 years, followed by those aged 0–04 years, and 10–14 years.

Virology:

- In the year-to-date, 65% of notifications of laboratory-confirmed influenza reported to the NNDSS were influenza A, of which 95% were influenza A(unsubtyped); 5% were influenza A(H1N1), and 1% were influenza A(H3N2)*. Influenza B accounted for

32.7% of notifications; influenza A&B accounted for 0.3% of notifications; and 2% of influenza notifications were untyped.

Vaccine match and effectiveness:

- Of the 1,915 samples referred to the WHOCC in the year-to-date, 97.4% of influenza A(H1N1) isolates, 82.8% of influenza A(H3N2) isolates, and 99.0% of influenza B/Victoria isolates characterised were antigenically similar to the corresponding vaccine components.
- It is too early to assess vaccine effectiveness for this season.

*Percentages may not total 100% due to rounding.

1. Introduction

Each year, the influenza virus changes and different strains can circulate in the population. Particular subtypes of influenza can affect different groups of the population more than others. Depending on the susceptibility of the population, the subtypes that are circulating and the changes to the virus itself, the influenza season can be very different year to year. Our surveillance systems help us to understand influenza activity, severity of the infection in individuals and impact of the illness on society in Australia. We are also able to monitor which influenza viruses are circulating, which populations might be more affected, the effectiveness of the vaccine, and any resistance to antiviral drugs that has developed.

1.1. National Influenza Surveillance System

This report presents an overview of influenza activity based on a number of complimentary systems. No one single system, including notification data, provides the full picture on influenza, because influenza is a common disease and its presenting symptoms are non-specific. The epidemiology of influenza is informed by a number of different systems based in the community, laboratories, primary care and hospitals, as well as notifiable diseases data, which includes officially reported deaths. The information in this report is reliant on the surveillance sources available to the Department of Health and Aged Care at the time of production.

- The **National Notifiable Diseases Surveillance System (NNDSS)** coordinates the national surveillance of more than 60 communicable diseases or disease groups. Notifications of laboratory-confirmed influenza are made to state or territory health authorities and supplied daily to the Australian Government Department of Health and Aged Care via the NNDSS for collation, analysis, and to assist in the coordination of public health responses.
- **Healthdirect** provides free health triage advice and information services by telephone and online, and can assist in identifying symptoms including those that may be classified as an ILI syndrome. Community level ILI syndromic trends are monitored using Healthdirect data.
- **FluTracking** is an online syndromic surveillance system which monitors ILI in the community.
- The **Australian Sentinel Practices Research Network (ASPREN)** is a year-round sentinel general practice (GP) surveillance system in which general and nurse practitioners report de-identified information on the number of ILI patient presentations seen in participating practices each week. It should be noted that in

addition to the overarching impacts of COVID-19 on influenza surveillance systems, interpretation of ASPREN's data from 2020 onwards should consider the following COVID-19 impacts:

- Changes in the health seeking behaviour at ASPREN sentinel sites due to the availability of telehealth and respiratory clinics may result in fewer presentations to General Practice (GP); and
- Changes to GPs swabbing at ASPREN sentinel sites, due to the availability of telehealth and respiratory clinics, may result in a lower number of swabs being undertaken by ASPREN reporters.
- The **Influenza Complications Alert Network (FluCAN)** conducts surveillance of severe influenza at sentinel hospitals across the country during the influenza season. The Paediatric Active Enhanced Disease Surveillance (PAEDS) network also contributes data on influenza via FluCAN.
- The **World Health Organization Collaborating Centre (WHOCC) for Reference and Research on Influenza** analyses influenza viruses currently circulating in the human population in Australia and other countries, to inform which strains should be included in annual seasonal influenza vaccines for the Northern and Southern Hemispheres.
- **Sentinel laboratory surveillance** systems provide fortnightly reporting of influenza testing. This includes the number of tests undertaken, the number of positive results, and the detected viruses. Sentinel laboratory site testing data are influenced by jurisdictional and laboratory testing practices, and should be interpreted with caution. Please note that tests conducted at sentinel laboratory sites may include samples taken from people in home or hotel quarantine for COVID-19, and may not reflect respiratory viruses circulating in the community alone.

1.2. Data considerations

- NNDSS laboratory-confirmed influenza surveillance case definition
 - From 1 January 2022, the [NNDSS surveillance case definition for laboratory-confirmed influenza](#) was updated to remove Point 5: 'Single high titre by complement fixation test (CFT) or haemagglutination inhibition (HAI) to influenza virus' from the list of laboratory definitive evidence.
 - This change has minimal impact on the interpretation of influenza notification trends, with the change ensuring consistency with the influenza laboratory case definition. For further information, please refer to the [NNDSS laboratory-confirmed influenza case definition Technical Supplement](#).
- Data in this summary is reported by International Organization for Standardization (ISO) 8601 weeks, with the week ending on Sunday. Throughout the summary, where the year-to-date is presented, this includes data from 1 January to 9 July. NNDSS data are analysed and reported based on diagnosis date, which is the true onset date of a case if known, otherwise it is the earliest of the specimen date, the notification date, or the notification received date. NNDSS data were extracted on Thursday 13 July 2023.
- In interpreting these data, it is important to note that changes in notifications over time may not solely reflect changes in disease prevalence or incidence. Depending on the disease, the number of notifications may be influenced by changes in testing policies;

changes in case definitions; changes in testing practices and screening programs; the use of less invasive and more sensitive diagnostic tests; and periodic awareness campaigns.

- In particular, analyses including data from 2020 and 2021 should be interpreted with caution. Influenza activity in 2020 and 2021 was unusual due to the suppression of influenza virus circulation because of COVID-19 mitigation measures. Data from these years may reduce five-year averages and affect analyses of usual seasonal trends. Therefore the years 2020 and 2021 are excluded in this report when comparing the current season to historical periods when influenza virus has circulated without public health restrictions. Where referenced, the five-year average in this report refers to the average of data from the years 2016, 2017, 2018, 2019, and 2022.
- Due to the dynamic nature of the NNDSS and other surveillance systems, data in this report are subject to retrospective revision and may vary from data reported in other national reports and reports by states and territories. Detailed notes on interpreting the data presented in this report are available at the Department of Health and Aged Care's [Australian Influenza Surveillance Report website](#). While every care has been taken in preparing this report, the Commonwealth does not accept liability for any injury or loss or damage arising from the use of, or reliance upon, the content of the report. Delays in the reporting of data may cause data to change retrospectively. For further details about information contained in this report please contact the Influenza Surveillance Team (flu@health.gov.au).

2. Analysis

2.1. Activity

Activity measures the capacity of the circulating influenza viruses to spread person to person and may be measured indirectly through systems that monitor influenza-like illness and more directly through systems that monitor laboratory-confirmed influenza.

2.1.1. Influenza-like illness (ILI)

FluTracking

- This fortnight (26 June to 9 July 2023), the average proportion of FluTracking participants reporting ILI (fever and cough) was 1.18%, compared to 1.1% in the previous fortnight (Figure 1).
- The average proportion of FluTracking survey respondents reporting ILI has been stable this fortnight.

Sentinel General Practitioners (ASPREN)

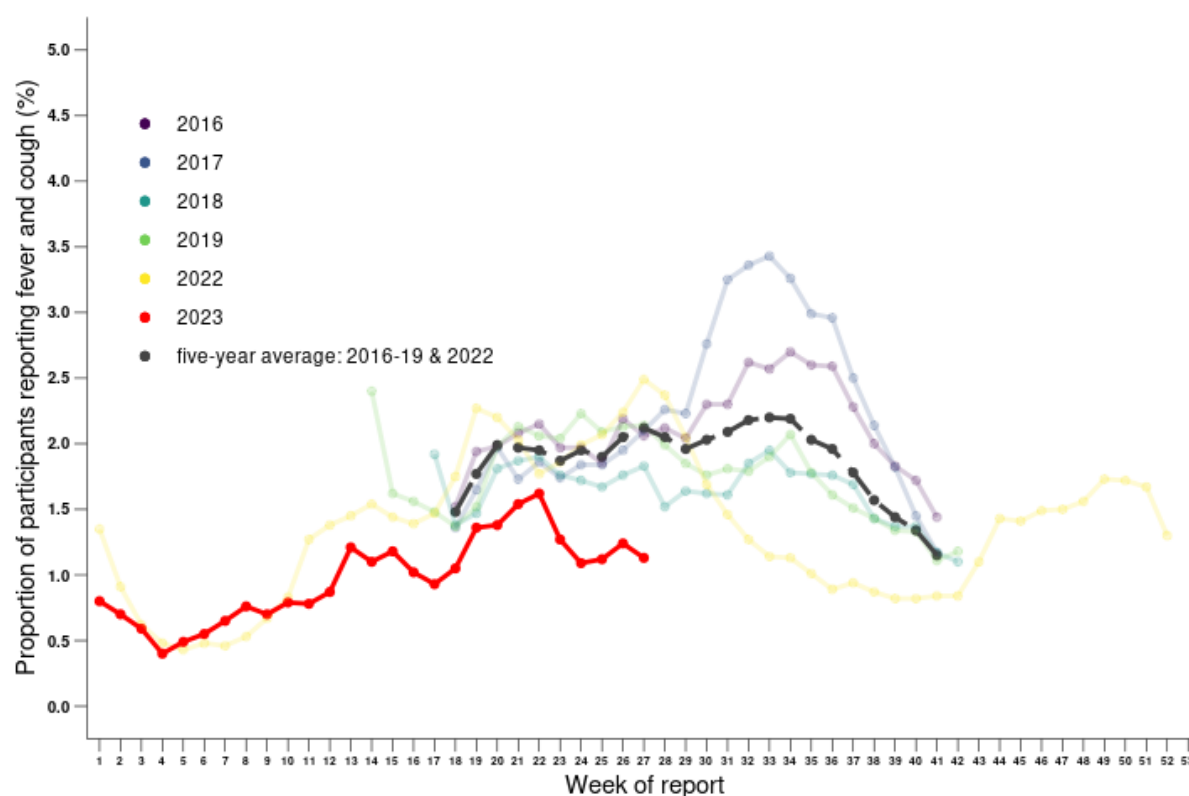

- This fortnight (26 June to 9 July 2023), an average of 8.5 per 1,000 consultations due to ILI were reported by sentinel ASPREN GPs, compared to 8.7 per 1,000 consultations in the previous fortnight (Figure 2).
- In the year-to-date, sentinel ASPREN GPs have reported between 0.5 to 9.6 consultations due to ILI per 1,000 consultations per week. The highest ILI rate to date this year was observed in week 24 (9.6 per 1,000 consultations) (Figure 2).
- In the year-to-date, 636 people presenting to a sentinel ASPREN GP with ILI were tested for respiratory viruses, of which 144 (22.6%) samples were positive for influenza.
- In the year-to-date, of those presenting to sentinel ASPREN GPs with ILI who were tested for respiratory viruses, 65.3% (415/636) tested positive for a respiratory virus. Among those positive for a respiratory virus, the most common virus reported was influenza (34.7%, 144/415). Other viruses detected included rhinovirus (29.4%), SARS-CoV-2 (15.4%), respiratory syncytial virus (9.4%), adenovirus (3.4%), and parainfluenza virus type-3 (2.7%).

Sentinel laboratories

- This fortnight (26 June to 9 July 2023) the most commonly detected respiratory viruses* by sentinel laboratory site and week were as follows:
 - New South Wales: Influenza A (both weeks);
 - South Australia: Rhinovirus (both weeks);
 - Tasmania: Influenza A (both weeks);
 - Victoria: Picornavirus and SARS-CoV-2 (week 26); and Picornavirus, SARS-CoV-2, Adenovirus, and RSV (week 27);
 - Western Australia: Influenza A (both weeks).

*Excludes SARS-CoV-2 for laboratory data reported by WA.

Figure 1: Proportion of fever and cough among FluTracking participants, Australia, 2016 to 09 July 2023, by year and week of report^{*^}

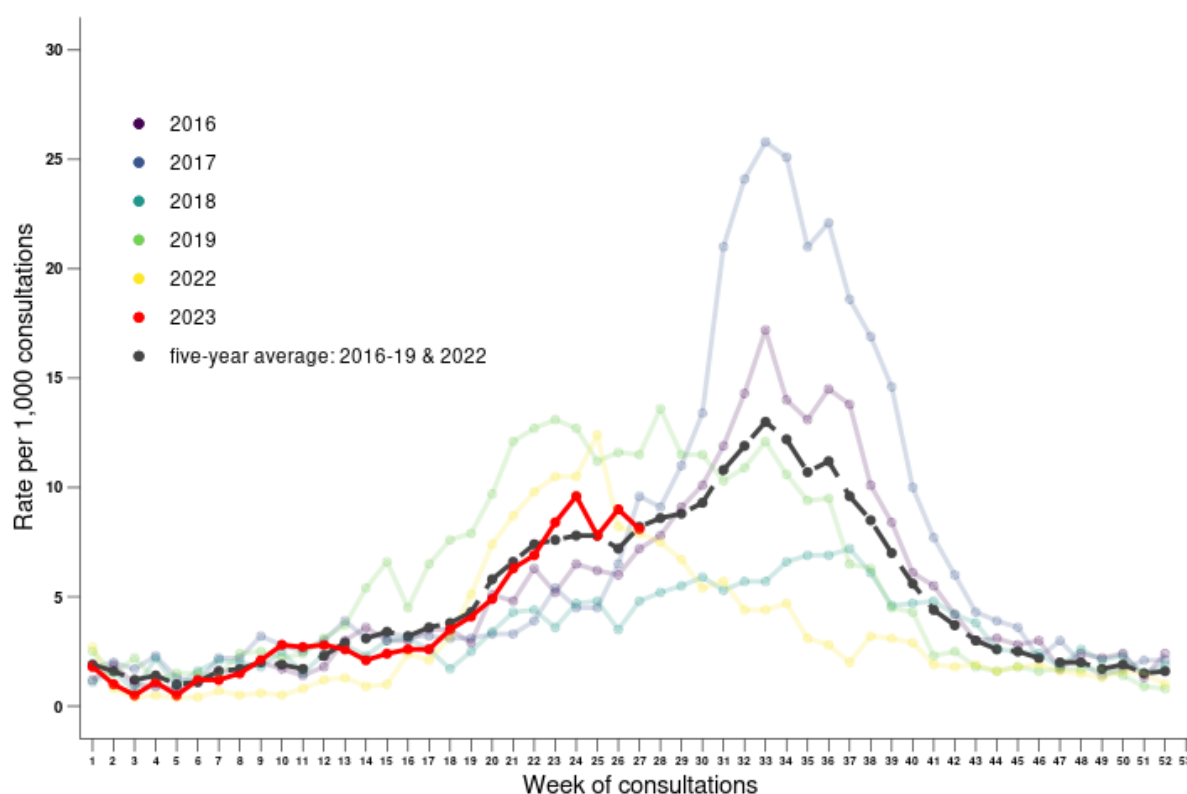

Source: FluTracking

^{*}All data are preliminary and subject to change as updates are received, with most recent weeks considered particularly subject to revisions.

[^]FluTracking have expanded their reporting period from 2020 onwards due to COVID-19. As such, five-year historical comparisons are not available for data reported before May and after October for any year before 2020. The years 2020 and 2021 are excluded when comparing the current season to historical periods when influenza virus has circulated without public health restrictions. Please refer to Data considerations for interpretation of the five-year average.

Figure 2: Unweighted rate of ILI reported from ASPREN sentinel GP surveillance systems, Australia, 1 January 2016 to 9 July 2023, by year and week[^]

Source: ASPREN

*All data are preliminary and subject to change as updates are received, with most recent weeks considered particularly subject to revisions. The years 2020 and 2021 are excluded when comparing the current season to historical periods when influenza virus has circulated without public health restrictions. Please refer to Data considerations for interpretation of the five-year average.

[^]Please refer to surveillance system description for notes on impact of COVID-19 on ASPREN data.

2.1.2. Laboratory-confirmed influenza

National notification data (NNDSS):

- There were 32,132 laboratory-confirmed influenza notifications with a diagnosis date this fortnight (26 June to 9 July 2023), compared to 30,255 notifications in the previous fortnight (Figure 3).
- In the year-to-date, there have been 149,989 notifications of laboratory-confirmed influenza to the NNDSS. This is a national notification rate of 577 cases per 100,000 population.

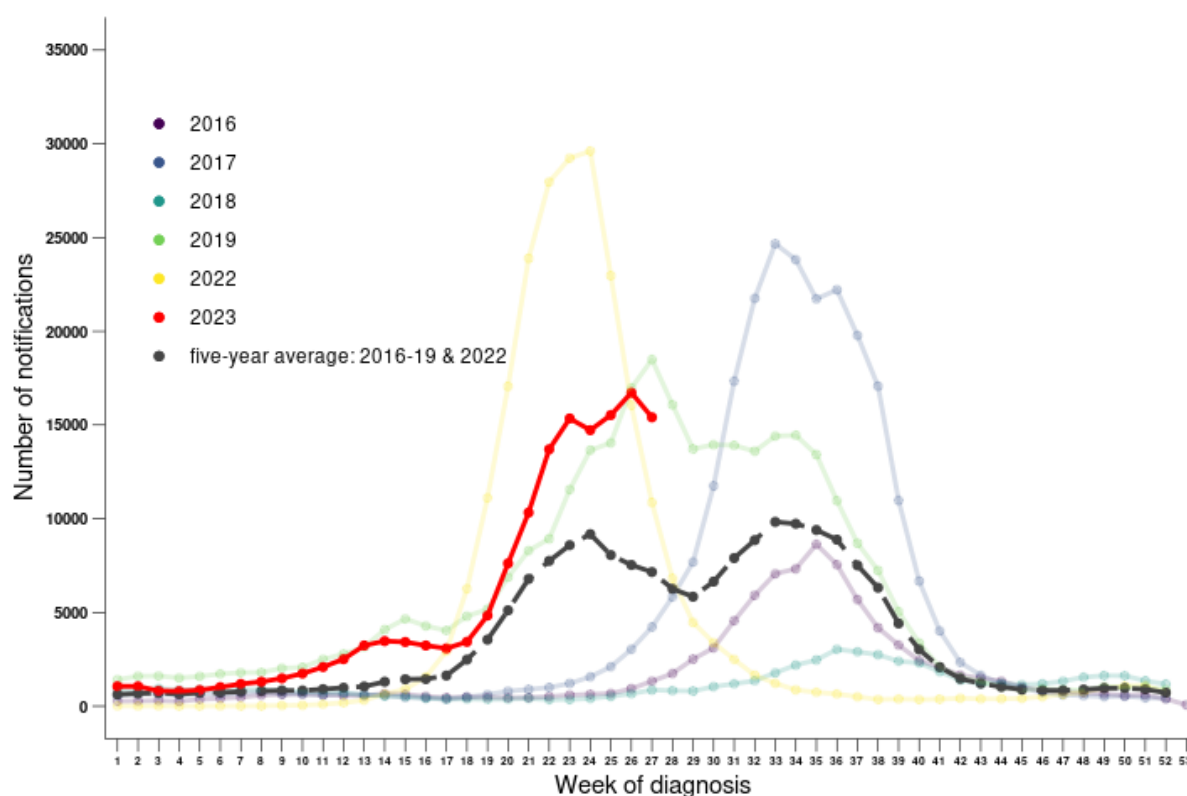

ASPREN

- In the year-to-date, there have been 144 (22.6%) influenza detections among the 636 ILI cases presenting to sentinel GPs who were tested for respiratory viruses.

Sentinel laboratories

- This fortnight (26 June to 9 July 2023), of the 23,636 samples tested across sentinel laboratories, 12.9% (n=3,056) have been positive for influenza, compared to 10.8% in the previous fortnight (Figure 4).
- Of the 237,108 samples tested across sentinel laboratories in the year-to-date, 5.7% (n=13,476) have been positive for influenza.

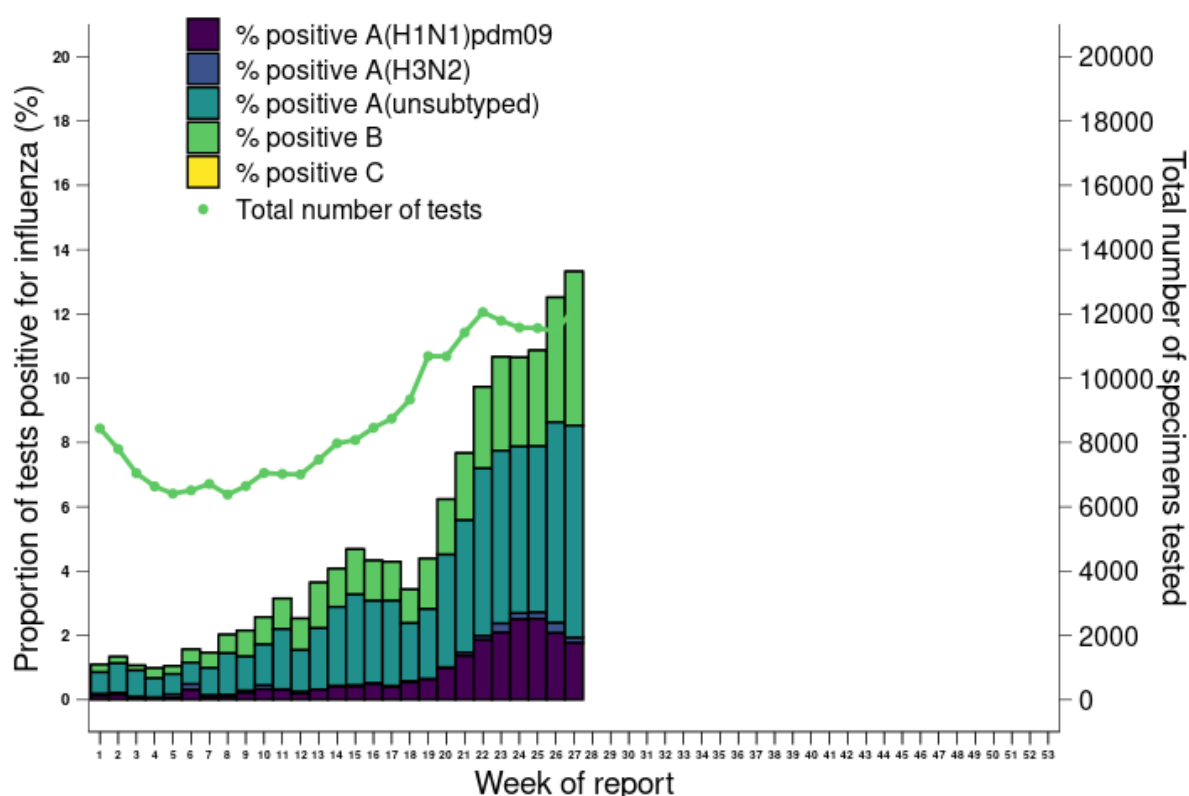

Figure 3: Notifications of laboratory-confirmed influenza, Australia, 1 January 2016 to 9 July 2023, by year and week of diagnosis*

Source: NNDSS

*NNDSS notification data provided for the current and most recent weeks may be incomplete. All data are preliminary and subject to change as updates are received, with most recent weeks considered particularly subject to revisions. The years 2020 and 2021 are excluded when comparing the current season to historical periods when influenza virus has circulated without public health restrictions. Please refer to Data considerations for interpretation of the five-year average.

Figure 4: Proportion of sentinel laboratory tests positive for influenza and total number of specimens tested, 1 January to 9 July 2023, by subtype, year and week*

Source: Sentinel laboratories

*Total number of tests include all specimens that were tested for influenza, including multiplex panels used to test for SARS-CoV-2. Testing methodologies vary across jurisdictions and laboratories. All data are preliminary and subject to change as updates are received, with most recent weeks considered particularly subject to revisions.

2.1.3. Geographical distribution of influenza activity

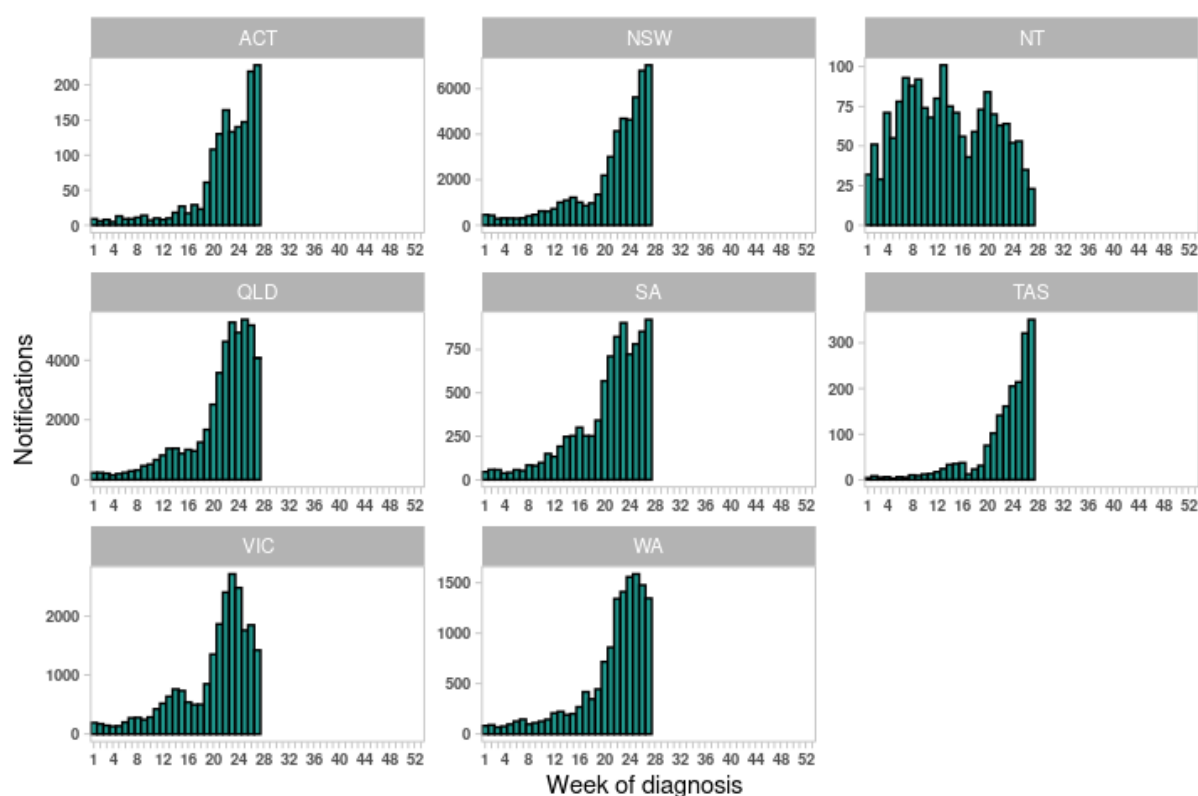

National notification data (NNDSS):

- In the year-to-date, influenza notification rates have been highest in Queensland (896 notifications per 100,000 population) followed by the Northern Territory (691 notifications per 100,000 population) (Table 1).
- This fortnight (26 June to 9 July 2023), influenza activity has increased in half of the jurisdictions, and has decreased in the others (Figure 5).

Table 1: Laboratory-confirmed influenza notifications to the NNDSS and notification rate per 100,000 population, 1 January to 9 July 2023

Jurisdiction	ACT	NSW	NT	QLD	SA	TAS	VIC	WA	Total
Number of notifications	1,563	50,929	1,733	47,670	9,025	1,863	23,408	13,798	149,989
Notification rate per 100,000 population	342	625	691	896	496	326	354	495	577

Figure 5: Notifications of laboratory-confirmed influenza*, 1 January to 9 July 2023, by state or territory and week of diagnosis

Source: NNDSS

*NNDSS notification data provided for the current and most recent weeks may be incomplete. All data are preliminary and subject to change as updates are received, with most recent weeks considered particularly subject to revisions.

For further information regarding influenza activity at the jurisdictional level, please refer to the following State and Territory health surveillance reports:

- ACT: [ACT Influenza Report](#)
- NSW: [Respiratory surveillance reports](#)
- NT: [The Northern Territory Disease Control Bulletin 1991 - current](#) (Influenza section)
- QLD: [Statewide Weekly Influenza Surveillance Report](#)
- SA: [Weekly Epidemiological Summary](#) (Influenza section)
- TAS: [fluTAS Reports](#)
- VIC: [Influenza Surveillance Reports](#)
- WA: [Virus WAtch](#)

2.2. Severity

Severity is a measure of adverse outcomes or complications as a result of ILI such as hospital referrals, admissions, need for intensive care, and deaths. Measuring and understanding the severity of circulating influenza is difficult to establish at the beginning, or during a low, influenza season. The proportion of confirmed influenza cases with serious outcomes might be skewed initially because there are only a small number of people notified. This means that the measure of severity will vary substantially fortnight to fortnight until numbers are sufficiently high and there is enough data for measurements to stabilise. An assessment of severity can be provided once the signals become clearer.

FluCAN:

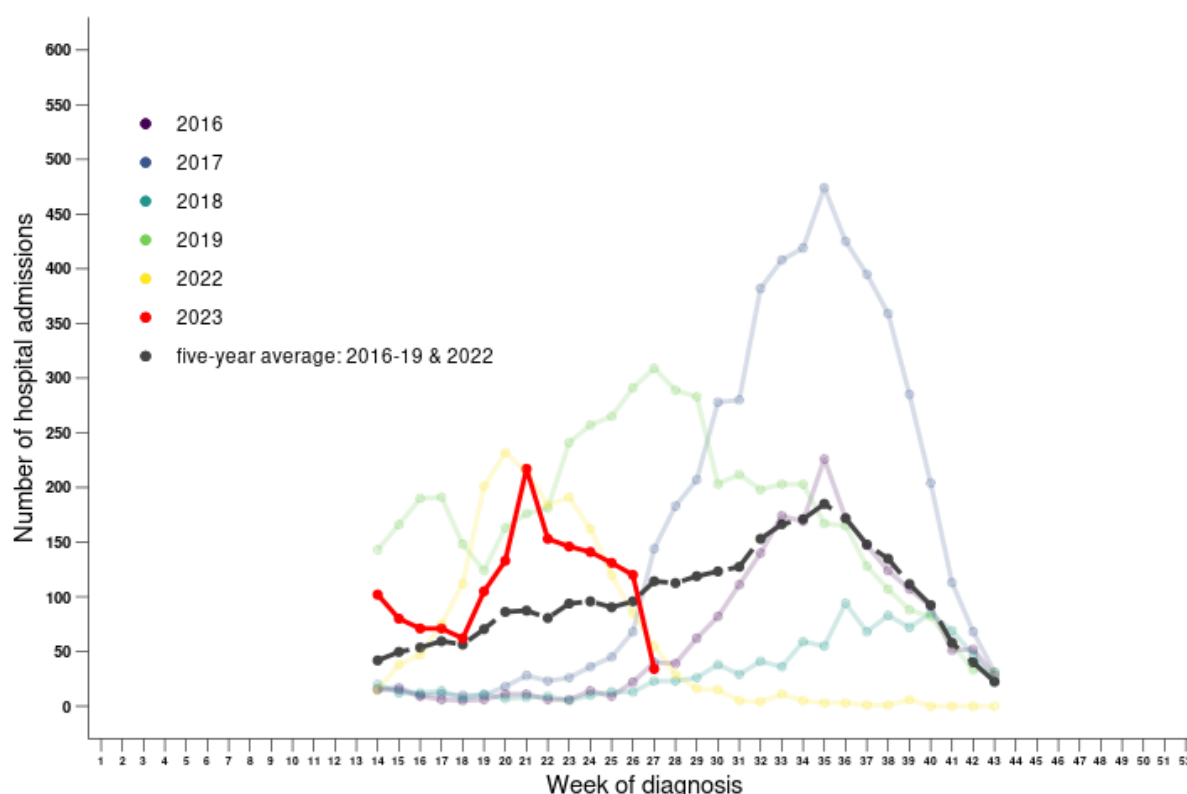

- This fortnight (26 June to 9 July 2023), there have been 154 hospitalisations due to influenza across FluCAN sentinel hospital sites, of which 9 (5.8%) cases were admitted to ICU (Figure 6).
- Since seasonal surveillance commenced in April 2023, there have been 1,568 sentinel hospital admissions due to confirmed influenza, of which 104 (6.6%) were admitted directly to ICU.

National notification data (NNDSS):

- In the year-to-date, of the 149,989 notifications of laboratory-confirmed influenza, there have been 134 influenza-associated deaths notified to the NNDSS.
- 81% of influenza-associated deaths were attributed to influenza A(unknown subtype), 10% to influenza B, 8% to influenza A(H1N1), and 1% to influenza A(H3N2).
- The median age of deaths notified was 76 years.

Note: the number of influenza-associated deaths reported to the NNDSS does not represent the true mortality associated with this disease. The number of deaths is reliant on the follow up of cases to determine the outcome of their infection. The follow up of cases is not a requirement of notification and are only inclusive of laboratory-confirmed cases of influenza. Due to retrospective revision, the variation across jurisdictions in methodology, representativeness, and timeliness of death data, and reporting of an outcome of infection not being a requirement of notification, year on year comparisons of deaths in notified cases of influenza may not be reliable.

Figure 6: Number of influenza hospitalisations at sentinel hospitals, from April to October, 2016 to 2023 by year and week of diagnosis*

Source: FluCAN

*All data are preliminary and subject to change as updates are received, with most recent weeks considered particularly subject to revisions. The years 2020 and 2021 are excluded when comparing the current season to historical periods when influenza virus has circulated without public health restrictions. Please refer to Data considerations for interpretation of the five-year average.

2.3. Impact

Impact measures how influenza affects society, including stress on health-care resources and societal and economic consequences.

FluTracking

- This fortnight (26 June to 9 July 2023), the average proportion of FluTracking participants reporting ILI and taking time off regular work duties while unwell was 0.81%, compared to 0.80% in the previous fortnight.
- The proportion of FluTracking survey respondents reporting having ILI and taking time off regular duties while unwell has stabilised this fortnight.

FluCAN:

- Since seasonal surveillance commenced in April 2023, there have been 1,568 sentinel hospital admissions, of which 104 (6.6%) were admitted directly to ICU.

2.4. At-risk populations

At-risk populations are people who may be more susceptible to infection with the influenza virus and/or who may be more likely to experience severe outcomes from their infection.

National notification data (NNDSS):

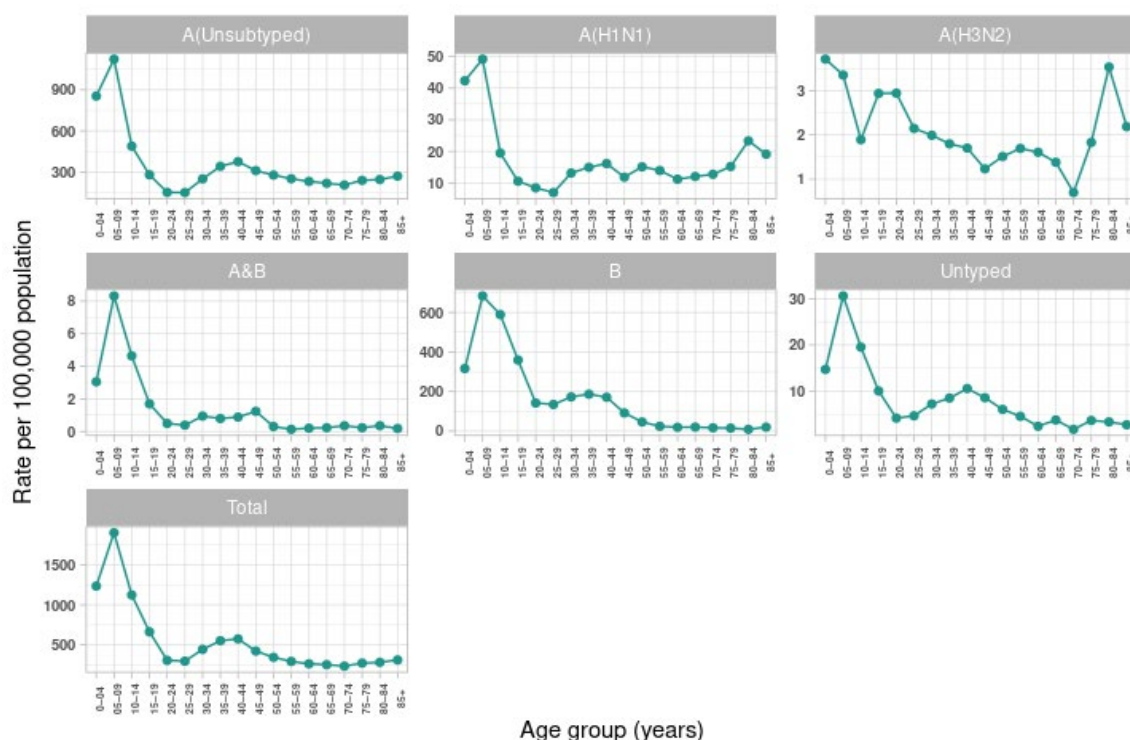

- In the year-to-date, notification rates have been highest in people aged 05–09 years (1,898 notifications per 100,000 population), followed by those aged 0–04 years (1,234 notifications per 100,000 population), and those aged 10–14 years (1,123 notifications per 100,000 population).
- In the year-to-date, influenza A accounted for the highest rate of notifications across all age groups (Figure 7).

FluCAN:

- Since seasonal surveillance commenced in April 2023, 71% of people admitted with confirmed influenza across sentinel hospital sites were children aged younger than 16 years*, 16% were adults aged 16 to 64 years, and 13% were adults aged 65 years or older.
- Of children aged younger than 16 years admitted with confirmed influenza to date, 5.9% were admitted directly to ICU, compared to 12.2% of adults aged 16 to 64 years, and 3.9% of adults aged 65 years or older.

*Hospital admissions in children under 16 years of age are over-represented in the FluCAN data in order to provide increased information on this at-risk population. The age distribution of hospital admissions in the FluCAN sentinel surveillance system may not reflect the age distribution of all influenza admissions nationally.

Figure 7: Rate of notifications of laboratory-confirmed influenza, Australia, 1 January to 9 July 2023, by age group and subtype*

Source: NNDSS

*All data are preliminary and subject to change as updates are received.

2.5. Virology

National notification data (NNDSS):

- Of the 32,132 notifications of laboratory-confirmed influenza reported to the NNDSS this fortnight (26 June to 9 July 2023), 50.0% (n=16,070) were influenza A(unsubtyped); 46.2% (n=14,859) were influenza B; 1.8% (n=588) were influenza A(H1N1); and 1.5% (n=493) were influenza untyped. 0.2% (n=66) were influenza A(H3N2). 0.2% were influenza A&B (n=56)
- In the year-to-date, 65% of notifications of laboratory-confirmed influenza reported to the NNDSS were influenza A (98,182/149,989), of which 95% were influenza A (unsubtyped); 5% were influenza A(H1N1); and 1% were influenza A(H3N2). Influenza B accounted for 32.7% of notifications (49,119/149,989); influenza A&B accounted for 0.3% of notifications (387/149,989); and 2% of notifications were untyped (2,301/149,989).
- In the year-to-date, influenza A has accounted for the majority of influenza notifications in most jurisdictions. In the Northern Territory however, influenza B still accounts for the highest proportion of notifications (Figure 9).

ASPREN

- In the year-to-date, there have been 144 influenza-positive samples detected through ASPREN GPs. Of these, 68% (98/144) were influenza A, of which 81% (79/98) were H1N1; 9% (9/98) were H3N2; and 10% (10/98) were A(unsubtyped). 32% (46/144) were influenza B, of which 89% (41/46) were B untyped, and 11% (5/46) were B/Victoria.

FluCAN

- Since seasonal surveillance commenced in April 2023, of the 1,568 hospital admissions across sentinel hospitals, 69.4% (1,088/1,568) were due to influenza A, 30.1% (472/1,568) were due to influenza B, and 0.5% (8/1,568) were due to influenza A&B. Of the admissions due to influenza A, 78.8% (857/1,088) were A(unsubtyped), 19.8% (215/1,088) were A(H1N1), and 1.5% (16/1,088) were A(H3N2).
- Of the 104 patients admitted directly to ICU, 71.2% (74/104) were due to influenza A, and 28.8% (30/104) were due to influenza B. Of the ICU admissions due to influenza A, 66 were A(unsubtyped), 7 were A(H1N1), and 1 was A(H3N2).

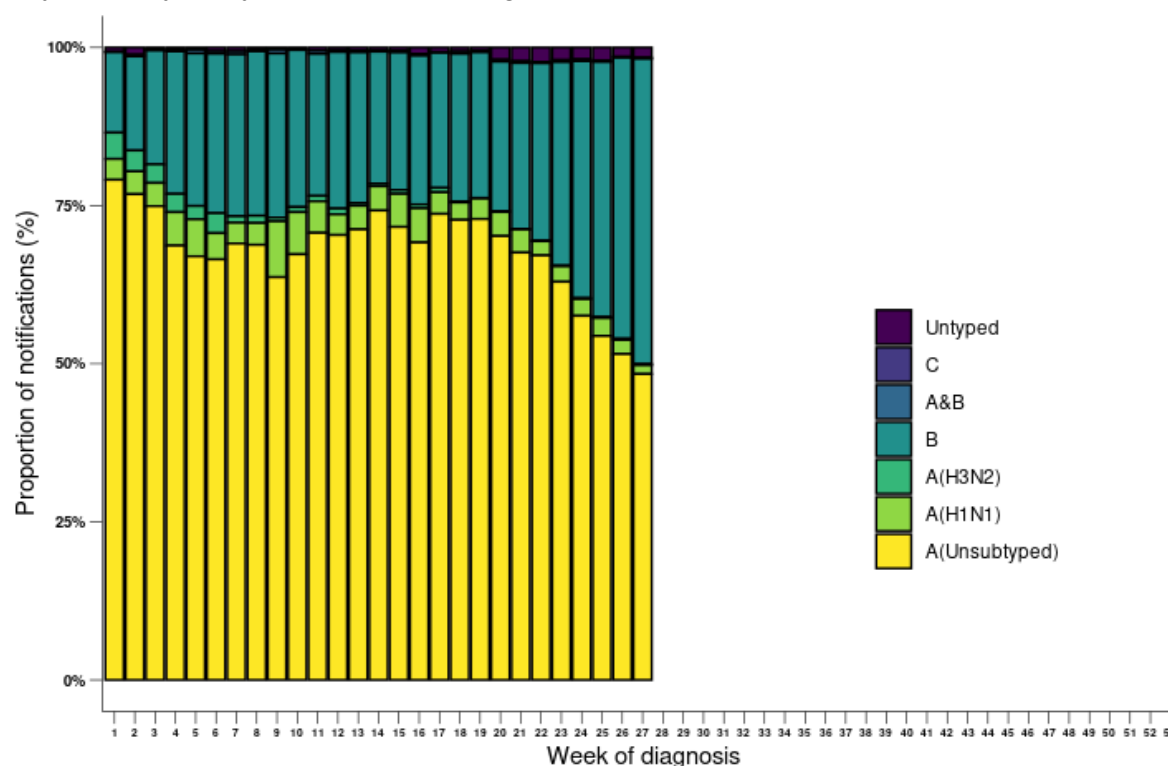

Sentinel laboratories

- Of the 13,477 influenza positive samples in the year-to-date, 70.4% (9,486/13,477) were influenza A, of which 74.3% (7,048/9,486) were influenza A(unsubtyped); 23.0% (2,178/9,486) were A(H1N1), and 2.7% (258/9,486) were A(H3N2). Influenza B accounted for 29.6% (3,991/13,477).

WHOCC

- From 1 January to 9 July 2023, the WHOCC characterised 1,915 influenza viruses, of which 50% (966/1,915) were influenza A(H1N1), 14% (261/1,915) were influenza A(H3N2), and 36% (688/1,915) were influenza B/Victoria (Table 2).
- Of the influenza A(H1N1) samples tested for neuraminidase inhibitor resistance, 1% (n=2) demonstrated reduced inhibition to Oseltamivir. None of the influenza A(H3N2) or influenza B/Victoria samples tested for neuraminidase inhibitor resistance demonstrated reduced inhibition to Oseltamivir or Zanamivir.

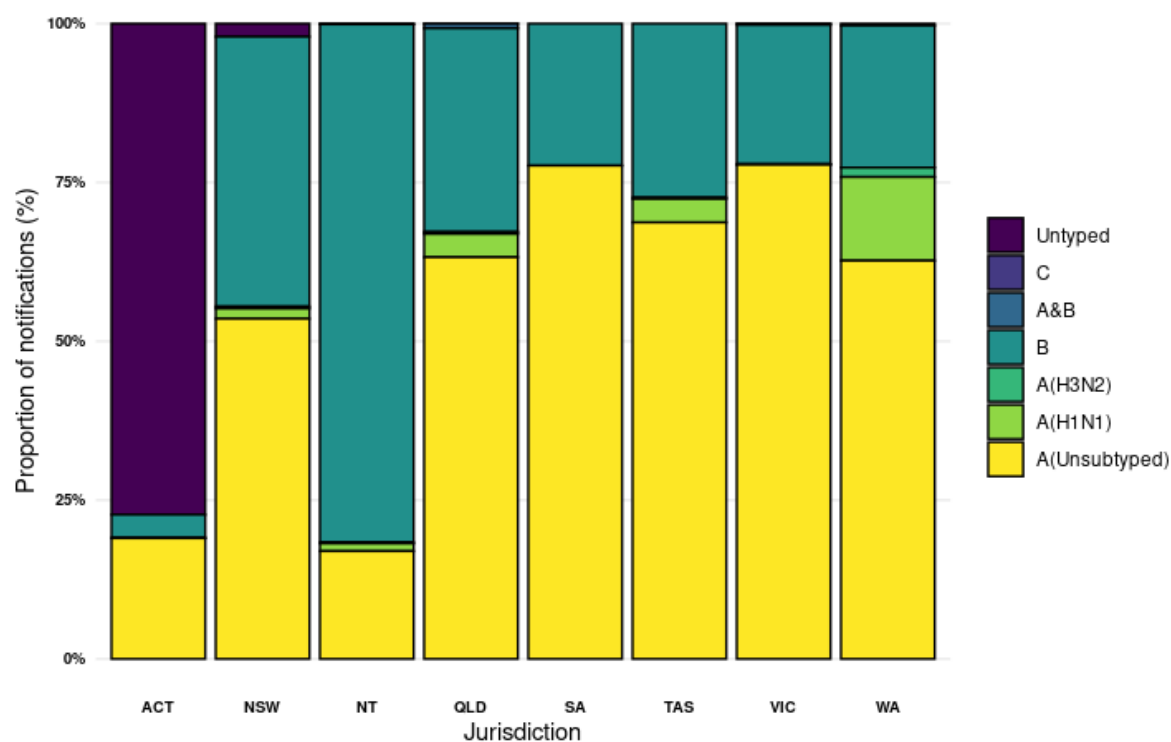

Figure 8: Percent of notifications of laboratory-confirmed influenza, Australia, 1 January to 9 July 2023, by subtype and week of diagnosis*

Source: NNDSS

*NNDSS notification data provided for the current and most recent weeks may be incomplete. All data are preliminary and subject to change as updates are received.

Source: NNDSS

*NNDSS notification data provided for the current and most recent weeks may be incomplete. All data are preliminary and subject to change as updates are received. As of 22 May 2023, subtyping data are not available for the ACT, until further notice.

Table 2: Australian influenza viruses typed by haemagglutination inhibition (HI) assay from the WHOCC, 1 January to 9 July 2023*

Strain	ACT	NSW	NT	QLD	SA	TAS	VIC	WA	Total
A(H1N1) pdm09	64	117	56	63	46	55	546	19	966
A(H3N2)	13	60	4	80	27	4	60	13	261
B/Victoria lineage	9	92	354	15	17	8	159	34	688
B/Yamagata lineage	0	0	0	0	0	0	0	0	0
Total	86	269	414	158	90	67	765	66	1,915

Source: WHOCC

*Viruses tested by the WHOCC are not necessarily a random sample of all those in the community. State indicates the residential location for the individual tested, not the submitting laboratory. There may be up to a month delay on reporting of samples.

2.6. Vaccine match and effectiveness

WHOCC

- Of the 1,915 samples referred to the WHOCC in the year-to-date, 97.4% (941/966) of influenza A(H1N1) isolates, 82.8% (216/261) of influenza A(H3N2) isolates, and 99.0% (681/688) of influenza B/Victoria isolates have been antigenically similar to the corresponding vaccine components.

Australian Influenza Vaccines Composition 2023

- All 2023 southern hemisphere [seasonal influenza vaccinations](#) registered for use in Australia are quadrivalent influenza vaccines (QIVs).
- The influenza virus strains included in egg-based QIVs in Australia in 2023 are:
 - A/Sydney/5/2021 (H1N1) pdm09-like virus;
 - A/Darwin/9/2021 (H3N2)-like virus;
 - B/Austria/1359417/2021 (B/Victoria lineage)-like virus; and
 - B/Phuket/3073/2013 (B/Yamagata lineage)-like virus.
- The influenza virus strains included in cell-based QIVs in Australia in 2023 are:
 - A/Sydney/5/2021 (H1N1) pdm09-like virus;
 - A/Darwin/6/2021 (H3N2)-like virus;
 - B/Austria/1359417/2021 (B/Victoria lineage)-like virus; and
 - B/Phuket/3073/2013 (B/Yamagata lineage)-like virus.

Vaccine effectiveness

The best way to determine how well the vaccine protects against circulating viruses during the season is by determining the vaccine effectiveness. Vaccine effectiveness is usually estimated from observational studies and is calculated after the end of the influenza season, though interim analyses are sometimes available where there is sufficient data.

It is too early to assess vaccine effectiveness for this season.
