@health.gov.au> **Subject:** RE: TGA/TAAD matters [SEC=OFFICIAL]

Sounds good.

I'll send an invite.

Re the ACMD submission, could I also look at Attachments 3 and 4? (I have 1&2: the Cochrane review and the Jones et al article).

I'll send you the TAAD Utilisation review, in confidence, FYI. Just in the interests of improving the TAAD/TGA interface. We elaborated on TGA's feedback on the Jones et al study following a discussion with <sup>\$22</sup> , alongside an analysis of Casemix and MBS data.

The way we integrate our respective pieces of work to get the best whole-of-system outcome is the next phase of the discussion...

Do you think <sup>\$22</sup> would like to be invited to this meeting?

THIS POCUMENT OF MENT OF THE PRESED OF THE P

## **SPINAL CORD STIMULATORS**

### SYSTEMATIC REVIEWS SUMMARIES

1. A review of spinal cord stimulation systems for chronic pain (Verrills, 2016) AUSTRALIAN STUDY

- The most recent systematic and comprehensive review of the effectiveness of SCS in treating chronic spinal pain demonstrated that there is a significant (Level I–II) evidence for SCS as a treatment for lumbar FBSS, where conventional medical management has failed.
- Furthermore, there is now Level I evidence for high-frequency stimulation but only limited evidence for burst stimulation.
- In another recent and extensive review and meta-analysis of conventional SCS, more than half of all patients experienced significant pain relief. The authors observed that this was maintained for a mean follow-up period of 24 months.
- These reviews above demonstrate that traditional SCS is an effective treatment option for a cohort that is notoriously difficult to treat.
- The literature, when viewed historically, must be tempered by the developments in skills, application, and technological advances.
  - Hence, the traditional SCS papers have often reported successful pain relief as an undifferentiated generic pain that is not specific to the site of the primary or greatest pain (eg, back or leg).
  - This observation is important because conventional SCS therapy has historically been prescribed for limb pain and has had only limited success in managing back pain.
  - Recent studies that have included back pain as the primary source have involved HF10 therapy at 10,000 Hz; this therapy has evolved to better capture significant back, leg, and radicular pain.
- Tolerance to SCS has been observed in patients where pulse amplitude needs to be increased to achieve the same analgesic benefit over time and/or efficacy has been lost.
  - Tolerance cannot be predicted
  - Data pertaining to HF10 SCS have demonstrated no tolerance at this point.
- Despite strict criteria for patient selection, a substantial number of patients fail to achieve optimal pain relief with SCS.
  - A number of factors have been identified as possible indicators for treatment failure including tobacco and drug use, age, and lengthy delay between times of original pain onset to SCS implant.
- DRG SCS has been demonstrated as effective in multiple etiologies, including FBSS, CRPS, and chronic postsurgical pain.
  - A recent study reported 1 year outcomes for DRG with overall pain scores reducing from 77.6 to 33.6 (P<0.005)</li>
  - Back pain reduced from 74.5 to 39.7 (P<0.05), and leg pain reduced from 74.6 to 28.7 (P<0.0005).</li>

- The most compelling pain reduction happened for foot pain with scores reducing from 81.4 to 22.0 (P<0.05).
- Approximately 60% of the DRG SCS patients reported >50% improvement in their pain, and the pain localized to the back, legs, and feet was reduced by 42%, 62%, and 80%, respectively.
- Other outcome parameters including quality of life, mood, and satisfaction were improved and maintained throughout the 12 months.
- The Accurate study is a US pivotal RCT between DRG SCS and traditional SCS Medtronic system
  - The largest RCT in the history of CRPS and causalgia, running from 2013 with primary completion estimated for 2018.
  - The sample size for the study is 152; with 76 randomized to DRG SCS and 76 to the control arm using Medtronic traditional SCS.
  - Superiority was demonstrated in the DRG SCS group with 81% of patients achieving
     >50% pain reduction and meeting the primary endpoint at the 3-month mark, and
     74% maintaining that primary endpoint at 12-month follow-up.
  - The traditional SCS arm demonstrated 56% of patients having >50% pain reduction at 3 months and 53% maintaining this through 12 months.
  - It was noted that 70% of patients achieved >80% pain reduction in the DRG group versus 52% in the Medtronic group.
- The Sunburst study ran from 2013-2016.
  - It is a prospective randomized, non-inferiority controlled trial
  - Patients who required to have pre-existing pain scores >6/10 and a >50% pain reduction in a traditional SCS trial using tonic stimulation.
  - The sample size for the study was 121 with 100 people randomized.
  - Analysis demonstrated superiority for burst stimulation over tonic stimulation
- The Senza RCT is a Level I study design run from 2012-2015
  - This is the first-ever RCT of two SCS therapies with patients randomized to HF10 SCS (Senza System) or traditional SCS commercially available, Precision Plus SCS system
  - o 198 patients were randomized with 101 to the HF10 SCS group and 97 to traditional
  - Of these, 90 HF10 SCS patients and 81 traditional SCS patients were subsequently implanted.
  - The primary endpoint of >50% back pain reduction at 3 months was achieved in 80.9% of the HF10 SCS group versus 42.5% of the traditional SCS group This met the criteria; At 12 months, this primary endpoint was met in 78.7% versus 51.3% of the patients.
  - Similarly, the primary endpoint for leg pain reduction was met in 80.0% of the HF10 SCS group versus 49.4% of the traditional SCS group
  - The responder rates for >50% leg pain reduction at 3 months was 83.1% in the HF10 SCS group and 55.0% in the traditional SCS group. The 12-month outcome data for the same groups were 78.7% versus 51.3%
  - This study demonstrated superiority of HF10 SCS to traditional SCS in all primary and secondary endpoints that has led to the labeling of HF10 therapy as superior to traditional low-frequency SCS by the FDA

Economical or cost efficiency

• Cost-efficacy studies show that despite significant initial costs, SCS compared with other conventional treatments available to chronic pain patients results in long-term reductions in health care costs, which offset the high initial treatment costs over time.44

Safety and tolerability

- In the literature, SCS is reported as a safe procedure due to its reversible and minimally invasive characteristics.
- Although catastrophic complications are possible, they are very rare.
- However, the incidence of minor complications of SCS has a higher incidence
- The complications are divided into three main categories: mechanical, biological, and technique-related.
  - Complications of a mechanical origin are more common than those of biological origin.
  - Incidence of minor complications 30-40% (readily reversible and generally resolved).
  - Hardware related complications 24-50%
  - o Mechanical complications eg lead fracture or disconnection 5-9%
  - Lead migration 0-27%; migration requiring intervention in <5%</li>
  - Implantable pulse generator failure occurred at a reported frequency of 1.7%
  - These complications are minimised by using the appropriate lead, anchoring and suturing techniques; minimising patient movement in first 3 months to allow scarring to form around leads
- One study demonstrated that lead migration of significance and requiring intervention in both the HF10 and traditional SCS arms occurred <5%. This most likely reflects improvements in both lead design and the anchoring systems used
- Biological complications include infection, allergic reaction, pain at implant site, implantable pulse generator seroma, epidural fibrosis, epidural hematoma, dural puncture, and, rarely, neurological injury.
  - The most common biological complication is infection with a rate between 3% and 8%, and the majority of these are superficial.
  - The occurrence of dural puncture is reported as between 0.3% and 2%.
  - Other adverse biological events such as epidural fibrosis, compressive phenomenon, or spinal cord injury, while serious, are rare.
- 2. Effectiveness of Spinal Cord Stimulation in Chronic Spinal Pain: A Systematic Review (Grider, 2016)

- Summary measures included 50% or more reduction of pain in at least 50% of the patients, or at least a 3-point decrease in pain scores and a relative risk of adverse events including side effects.
- Improvement for less than 12 months is considered as short-term and longer than 12 months is considered as long-term.
- Of the 3 randomized trials evaluating SCS, all of them reported effectiveness for short- and long-term relief

Table 4. Results of published studies of effectiveness of spinal cord stimulation in failed back surgery syndrome.

RA = randomized; AC = Active-control; SCS = spinal cord stimulation; CMM = conventional medical management; vs = versus; P = positive; N = negative; NA = Not applicable; U = undetermined; HF10 = 10 kHz high frequency therapy; HFSCS = high frequency spinal cord stimulation

# 3. SYSTEMATIC REVIEW OF EFFICACY OF SPINAL CORD STIMULATION FOR MANAGEMENT OF PAIN IN CHRONIC PANCREATITIS (Ratanake)

Background: Spinal cord stimulation (SCS) is frequently used to manage chronic pain syndrome in patients with chronic pancreatitis (CP). This systematic review aimed to summarise the indications and effectiveness of SCS in the management of pain associated with CP.

Materials and Methods: A systematic review employing Prisma methodology was performed through interrogation of the PubMed, Medline, EMBASE and Cochrane databases.

Results: Seven studies including sixty-six patients met the inclusion criteria. The patient groups included five case series and two observational cohort studies. The pooled mean age of the study group was 44 years and 23% (15/66) had alcohol induced CP. The SCS leads were commonly placed at the level of T5-6 near the anatomic midline of the spine. Patients reported a pooled mean reduction of visual analogue pain scores of 56% and a pooled mean reduction of morphine equivalent opioid use of 70% at the end of follow-up. In contrast to percutaneous leads, surgical leads showed a broader stimulation pattern, lower stimulation requirement and was associated with reportedly better longterm effectiveness.

Conclusion: This systematic review has shown that the use of SCS in patients with chronic pancreatitis may decrease pain, reduce opioid use and improve functional capacity. Further randomised, controlled trials are required to establish efficacy in the application of SCS for visceral abdominal pain from CP.

#### TGA Assessor summary:

- SCS may reduce pain and opiod use
- Further studies required
- 4. The Effectiveness of Spinal Cord Stimulation for the Treatment of Axial Low Back Pain: A Systematic Review with Narrative Synthesis (Conger, 2020)

- The reviewed studies were found to be heterogenous across patient populations, interventions (different SCS technologies), comparators (low-frequency SCS, conventional medical management, various lead configurations), and outcome measurement tools. For these reasons, meta-analysis of comparative measures of effect such as a proportion ratio or proportion difference was not performed.
- This is the first systematic review to examine the effectiveness of different SCS technologies specifically for long-term reduction of axial LBP in patients with or without concomitant leg symptoms.
- Review included 2 RCTs (four publications), 4 nonrandomized comparative studies, and 9 single-group cohort studies.
- Several studies did not use back pain as the primary outcome (many measured overall pain or leg pain) but did report back pain—specific scores.
   Secondary outcomes included medication use (opioid and nonopioid), measures of patient satisfaction, quality of life, and disability.
- Based on low-quality evidence, 10-kHz SCS appears effective beyond six months for axial LBP reduction in patients with predominantly axial spine pain and in those with mixed axial low back and leg pain.
- Improvements in pain relief, functional improvement, patient satisfaction, and reduced opioid use were seen
- Considering the consistently large magnitude and durable pain reductions observed in these studies, further controlled, investigator-initiated studies with long-term follow-up are needed to investigate the relative effectiveness of 10-kHz SCS on axial LBP compared with continued non neuromodulation management and compared with other SCS technologies to determine relative effectiveness.
- Only one study using burst SCS met inclusion criteria for this review.
  - A small, nonrandomized comparative study of 10-kHz SCS and burst modalities showed similar effectiveness between burst and 10-kHz SCS for the treatment of axial LBP, with similar associated improvement in sleep and physical function, however, this study included only 14 patients.
  - Despite its exclusion
- Previous studies indicate that traditional low frequency SCS is less effective for reducing axial LBP as compared with neuropathic leg pain.
- The PROCESS trial (2007) compared traditional low-frequency SCS to CMM and demonstrated a 48% responder rate for leg pain reduction at six months but failed to achieve meaningful axial LBP reduction.
- 5. Spinal Cord Stimulation vs Conventional Therapies for the Treatment of Chronic Low Back and Leg Pain: A Systematic Review of Health Care Resource Utilization and Outcomes in the Last Decade (Odonker 2019)

- 11 studies meeting inclusion criteria were analyzed, representing 31,439 SCS patients and 299,182 CT patients
  - o 6 of 11 studies evaluating SCS vs CT
    - SCS was associated with favorable outcomes and found to be more costeffective than conventional treatment approaches for chronic low back pain
  - The most common indication for SCS was failed back surgery syndrome (FBSS), which was evaluated in 6 of 11 studies.
    - Other indications included complex regional pain syndrome (CRPS), peripheral arterial disease (PAD), refractory angina pectoris (RAP), chronic back and leg pain, chronic axial low back pain, degenerative disc disease,

radiculitis, neuropathic leg and back pain, and chronic benign pain syndrome.

- Cost Analysis
  - In 6 of 11 studies analysing costs, SCS was associated with favourable outcomes in terms of cost-effectiveness and health resource utilization compared with conventional therapy
- Pain Relief
  - o Overall, 3 of 11 studies included pain relief outcomes
  - There was a large discrepancy in reported pain relief outcomes depending on the type of study and population evaluated
  - Some studies suggested that success rate (measured by a >50% improvement in leg pain) of SCS vs conventional treatment at 24 months was 16% vs 21%, respectively
  - Compared with conventional treatment, there was a 2.5-fold reduction in pain scores at six months, although no differences in reported pain scores, opioid use, or physical function were found at 24months
  - One study showed that 51% of patients achieved >50% improvement in leg pain intensity.
  - Another found that the probability of achieving >50% pain relief was 9.3% for CT and 58.5% for SCS
  - Studies among workers' compensation patients generally showed less pain relief from SCS compared with conventional treatments.
- Complications
  - Adverse events associated with SCS were reported in 3 of 11 studies
    - When lumbar surgery was compared with SCS, SCS resulted in a lower complication rate of 8.6% compared with 16.52% for lumbar surgery
    - Types of complications included renal, cardiac, neurological, pulmonary, DVT/PE, systemic infection, and pocket site wound infection.
    - The authors concluded that overall costs between SCS and lumbar surgery were similar, but SCS was associated with fewer complications and improved outcomes
  - Complications were noted as a major contributor to overall SCS expense
    - An annual complication rate of 19%/year for SCS b CT has been reported
- Quality Assessment and Level of Evidence Results of quality assessment and level of evidence, using the GRADE framework
  - 4 of 11 studies (36%) had moderate-quality evidence and
  - 7 of 11 (64%) had low-quality evidence supporting the primary outcome measures of higher costeffectiveness, higher percent reduction in opioid use, shorter hospitalizations, and lower resource utilization with SCS therapy compared with conventional management
- Risk of Bias Analysis
  - There was high publication bias in 7 of 11 studies (64%) and low publication bias in 4 of 11 studies (36%).
  - The majority of studies did not report any blinding of participants, personnel or outcome assessment, and allocation concealment.
  - Only one study was an RCT, but almost all studies (10/11) had complete data and, as far as estimable, little selective reporting bias
- 6. Spinal cord stimulation for low back pain (Protocol)

#### STUDY NOT COMPLETED

#### Description of the intervention

Spinal cord stimulation (SCS) involves implanting an electrical device in the lower back that generates electrical pulses and delivers them to the spinal cord via electrodes (Kemler 2000). Electrodes are positioned in the dorsal epidural space adjacent to the area of the spinal cord thought to be causing the pain.

The 'leads', containing sets of electrodes, can be implanted via laminectomy or percutaneously. Depending on the location and intensity of the person's pain, a clinician may select from a varying number and type of leads (uni-, bi-, or multi-polar), and parameters of stimulation (amplitude, pulse width, electrode selection). The device requires power from a battery pack implanted under the skin or transcutaneously via a radiofrequency transmitter. Parameters of stimulation can be adjusted wirelessly using a remote control (Mailis-Gagnon 2013).

Before a surgeon implants the device, current protocols usually require a screening period. Leads are temporarily placed percutaneously, and the clinician assesses the individual's response to the stimulation while they continue with usual activities. The screening phase lasts from days to weeks. A positive response is often defined as at least 50% pain relief (Kemler 2000). If the screening phase is positive, a surgeon may offer a laminectomy to permanently implant the stimulator and leads. Batteries for the stimulator systems can be rechargeable (stimulator type is known as a 'rechargeable implantable pulse generator (IPG)') or conventional (known as a 'conventional IPG'). Conventional IPGs require repeat surgeries to replace the battery.

#### How the intervention might work

The mechanism of action of SCS for low back pain is poorly understood. SCS was originally thought to work via the gate-control mechanism (Melzack 1965), that is, stimulation of part of the spinal cord interrupts transmission of pain-related information to the cortex. However, evidence of the eKects of SCS on the relay of pain-related information at the spinal cord in humans is limited (Meyerson 2000). In addition, SCS does not appear to influence pain in response to an experimentally induced noxious stimulus (Meyerson 2000). Other suggested mechanisms have included inhibition of the sympathetic nervous system (sympatholytic effect) (Kemler 2000), and interrupted transmission of pain-related

nerve impulses by the brain (supraspinal inhibition) (Meyerson 2000). It is unclear whether the mechanism of action differs in people with chronic low back pain, compared to those with leg pain, or those diagnosed with FBSS (Meyerson 2000).

Why it is important to do this review

SCS is thought to be helpful for chronic low back pain, sciatica and FBSS. The National Institute for Health and Care Excellence (NICE) recommends SCS for refractory neuropathic pain (NICE 2020). In 2014, the SCS market was estimated to be valued at 1.3 billion US dollars (USD) (PRWeb 2015). In the USA the average cost of implanting a stimulator is USD 30,000, plus USD 10,000 per annum for maintenance care if the person experiences complications. One study estimated that 12% of people who had SCS experienced at least one complication, such as lead migration or wound infection (Shamji 2015).

Evidence on the benefits and harms of SCS compared with placebo or no treatment, is limited. A Cochrane Review of efficacy in chronic pain was withdrawn because it was out of date (Mailis-Gagnon 2013). Grider 2016conducted a systematic review of SCS for low back pain and focused on a wide range of trials, including those that compared SCS with different stimulation regimens and various other control treatments of unknown efficacy. This made the true efficacy of the procedure difficult to determine. Grider 2016 did find three small trials that compared SCS to no treatment or placebo/sham (160 participants in total). The trials had mixed results. One small trial (n = 40) found no effect on pain intensity at four weeks compared with placebo SCS (device switched oK) (Perruchoud 2013). One hallmark 2007 trial by Kumar and colleagues (n =100) investigating SCS as an addition to 'conventional medical management' found a large effect on leg pain at six months (-26.7 (95% CI -40.4 to -13.0) points on a 100-point scale) (Kumar 2007). Because the 'conventional medical management' was not standardised or provided in a controlled way, the comparison was

essentially between SCS and no treatment.

There have been additional trials since the 2016 review. In 2019, Riogard and colleagues reported on the PROMISE trial (Rigoard 2019). Similar to the trial by Kumar and colleagues (Kumar 2007), PROMISE compared SCS plus 'optimal medical management' with 'optimal medical management' alone. The 'optimal medical management' was not standardised or controlled by the investigators and so the comparison was, once again, essentially between SCS and no treatment. At six months, the between-group difference in low back pain was 1.1 (95% CI 0.6 to 1.6) points on a 0 to 10 scale. The large effect on leg pain previously observed by Kumar and colleagues in 2007 was not replicated: at six months the effect was 1.3 (95% CI 0.7 to 1.9) points on 0 to 10 scale. The SCS Frequency Study, a small study (n = 24) that compared SCS treatment at three different frequencies against 'sham' SCS treatment (device is switched on but not delivering any stimulation), found that some SCS regimens were not superior to sham (Al-Kaisy 2018). In the Riogard trial, 18% of participants experienced a stimulator-related adverse event. New trials are also underway (e.g. MODULATE-LBP (Al-Kaisy 2020)) or have overdue results.

To date, the evidence from trials of SCS suggests that, compared with placebo or no treatment, the effects on low back pain and leg pain are uncertain. Another Cochrane Review is underway, examining the effect of SCS on any pain condition (O'Connell 2020). However, those authors have not planned a subgroup analysis focused specifically on people with low back pain. A focused Cochrane Review will help resolve some of the uncertainty regarding efficacy of SCS for people with low back pain, and help clinicians, people with low back pain and policymakers make decisions based on the best available evidence.

#### TGA Assessor summary:

- This study is under way but not complete
- Study Objectives:
  - 1. To assess the benefits and harms of spinal cord stimulators for people with low back pain, with or without leg pain.
- Types of outcome measures:

#### Major outcome measures

- a) Outcomes assessing benefits:
  - 1. Pain intensity: numeric rating scale (NRS), visual analogue scale, pain severity subscale of brief pain inventory
  - 2. Function: using various scales/scores
  - 3. Health-related quality of life: using various scales/scores
  - 4. Global assessment of efficacy: participant-rated improvement measured as per cent improvement or on categorical scale
- b) Outcomes assessing harms:
  - 1. Proportion of withdrawals due to adverse events
  - 2. Proportion of participants with adverse events: any adverse events reported (e.g. cardiovascular events, worsening of pain, fatigue, etc.)
  - 3. Proportion of participants with serious adverse events (defined as leading to hospitalisation, disability or death)

#### Minor outcomes

- a) Medication use: number and proportion of participants taking any pain medication, daily dose of opioids as a morphine equivalent dose, or as reported in trials
- b) Health care use: number of visits to any healthcare provider for care related to participant's back pain or management of the SCS, or both
- c) Work status: number and proportion of participants reported to have returned to work, work absences, or as reported in trials

7. A Systematic Review of the Cost-Utility of Spinal Cord Stimulation for Persistent Low Back Pain in Patients With Failed Back Surgery Syndrome (McClure 2020)

#### TGA Assessor summary:

SCS Technology and Cost-Effectiveness

- The types of delivery system used and the frequency and tonicity of the stimulation provided by the device are under heavy development. The use of a more novel paddle design and configuration has shown superior outcomes compared to traditional electrode size and placement.
- Other technological improvements include the use of SCS devices that provide stimulation at much higher frequencies (10 000 vs. 50-100Hz).
- A recent randomized trial demonstrated that not only do patients prefer the higher frequency SCS devices' lack of paraesthesia compared to traditional stimulation devices, the higher frequency devices also provide superior and more durable pain relief.
- A different stimulation method that also seemingly improves upon traditional stimulation methods provides SCS in a burst pattern rather than tonic stimulation.
- The burst stimulation method is more novel than the high frequency method. As such, studies assessing its efficacy at time points greater than a year remain unpublished.
- Literature that examined the cost-effectiveness of these more novel devices was not found.
- An improvement in SCS cost-effectiveness would result from prolonging the battery life of non-rechargeable devices. As it currently stands, the published literature that compared the cost-effectiveness of non-rechargeable and rechargeable devices showed a slight benefit to rechargeable devices. This is largely due to having fewer replacements over the patient's lifetime and the associated surgical costs.
- The industry standard device longevity for non-rechargeable devices is \*4.5 years. If a non-rechargeable device does not require replacement until after 4.5 years from initial implantation, it becomes more economical to utilize compared to the rechargeable models, given the initial device costs are similar. As such, if the cost of non-rechargeable devices could be maintained while simultaneously improving battery life, this would further improve cost-effectiveness of SCS devices.

Improving SCS Cost-Effectiveness With Refined Patient Selection

- An alternative method to improving the cost effectiveness of SCS devices is further refining patient selection.
- Several studies have analysed this; however, most of them utilize rather small sample sizes. Combining the findings from these studies, an ideal responder would not use tobacco, be of normal weight, and be free of psychiatric comorbidities other than anxiety.
- The data surrounding which age group might better respond to SCS for LBP is mixed.
- North et al found that patients who failed SCSdi and crossed over to re-operation failed to achieve adequate pain relief. This cross-over resulted in inferior outcomes for patients of lesser pain-relief achieved and lower patient satisfaction, both coming at higher costs as well; a patient who did not respond to SCS and underwent subsequent re-operation ended up costing more than double the average patient who just had re-operation and over 5 times the amount of a patient just receiving SCSdi.
- 8. Systematic Review of Research Methods and Reporting Quality of Randomized Clinical Trials of Spinal Cord Stimulation for Pain (McNicol 2021)

#### TGA Assessor summary:

• Review of 46 studies identified deficiencies in both reporting and methodology.

## 9. The Role of Spinal Cord Stimulation in Reducing Opioid Use in the Setting of Chronic Neuropathic Pain (Smith, 2022)

- The 17 studies examined in this review illustrate the ability of SCS to aid in the reduction of opioid use over a wide range of preimplantation doses at 12 months post implantation.
- 6 of the studies included showed 46% to 71.4% of participants were able to reduce their daily opioid dose from 25% to 64% from their preimplantation dose
- Likewise, 7 from 9 studies showed that participants were able to reduce their daily opioid dose from 20% to 48.6% from their preimplantation dose, with one study showing only a 7% dose reduction
- In a systematic review of 5 trials totaling 489 patients, Pollard and colleagues found that SCS patients were more likely to reduce their opioid consumption than patients using medical therapy alone.
- In a large, retrospective study of 5476 patients, Sharan et al found that > 91% of patients kept their implant over all opioid doses at 1 year, with the majority of patients maintaining or decreasing opioid dosage.
- The success of SCS in supporting the reduction in opioid dose is connected with its ability to reduce chronic pain.
- 6 of the 17 studies provided a percentage of patients who were able to discontinue opioid use at 12 months post implantation
  - These percentages varied from 1.5% to 42.8%.
  - In 2 of these studies, a correlation was made between a particular preimplantation opioid dose or dose range and an increased likelihood of discontinuation of opioid use
- Collectively, these studies suggest that a low preimplantation opioid dose may provide patients with the best chance of eliminating opioid use post-SCS implantation.
- Of note, in addition to increasing the possibility of opioid discontinuation, reduction in preimplantation opioid dose may also increase the effectiveness of SCS pain reduction.
- Preimplantation opioid use has been consistently shown to reduce the likelihood of pain remission after SCS.
- The precise reason for this diminution in effectiveness is unknown.
- Studies have shown:
  - At 1 and 2-year follow-up after SCS implantation, system explant was significantly associated with opioid use
  - Others have demonstrated that patients who do not use opioids before SCS implantation experience superior outcomes as compared with those patients who used opioids before surgery.
- SCS is an effective treatment for many types of chronic pain, with significant advantages over medical management alone in both pain relief and side effect profile.
- SCS can also lead to reduction or elimination of chronic opioid use.
- Current research supports the conclusion that SCS should not be reserved as a therapeutic of last resort, rather it should be considered earlier in the therapeutic process.
- Recent studies have demonstrated that longer pain-to-SCS time has been shown to correspond to a decreased efficacy of SCS, and increasing pain-to-SCS time is also associated with significant increases in health care resource utilization.
- Current studies demonstrate that SCS is most effective when used in patients who are not chronic opioid users before implantation.

## **FINAL COMMENTS**

- The SCS systems are used in quite complex chronic pain scenarios
- It appears that these systems have undergone design changes and improvements over the years, with newer version addressing past issues and concerns
- The high complication rates are acknowledged but the causes of these appear to be multifactorial in nature e.g Patient selection is crucial; the version of the device used etc
- Non-inferiority studies have shown that new iterations of SCS systems are superior to the older ones
- Although the cost-effectiveness analyses are based predominantly on overseas data, we would expect a similar outcome here
- Further data can be requested from manufacturers to determine if there is any areas of concern for the TGA regarding the numbers and types of complications being encountered in Australia. A comparison can then be made on whether this is consistent with the international experience.
  - It would be helpful is data could be provided for the following: patient demographics; therapy type eg burst/high/low frequency therapy; duration of treatment; numbers of patients who had resolution of symptoms and subsequent removal of SCS; what patients are told to do routinely following surgery; how frequent follow-up reviews are
  - Depending on the data we receive, I anticipate that we would need to also review the IFU/PIL and technique guides to ensure that risks are discussed and mitigated where possible

#### Spinal Cord Stimulators

Literature Summary

Brief summary:

These devices appear to be a last resort for many cases – the patient populations in the studies usually specified that patients had to be refractory to one or more medications.

The Cochrane review of Dec 2021 is an excellent synopsis of SCS risk.

They found that SCS is associated with complications including infection, electrode lead failure/migration and a need for reoperation/re-implantation. The level of certainty regarding the size of those risks is very low. The authors found very low-certainty evidence that SCS may not provide clinically important benefits on pain intensity compared to placebo stimulation. At six months follow-up their estimates suggest a 4% risk of infection, a 4% risk of lead failure/ displacement and an 11% risk of requiring reoperation/reimplantation. The authors found reports of some serious adverse events as a result of the intervention. These included autonomic neuropathy, prolonged hospitalisation, prolonged monoparesis, pulmonary oedema, wound infection, device extrusion and one death resulting from subdural haematoma.

It appears from initial analysis that the serious complications of neurological adverse events e.g. paralysis, spinal cord hematoma, dural puncture are rare. But lead migration is quite common and does require a surgical procedure to correct. Similarly, in the publication of concern by the group of PhD authors, found that as a proportion of the 'device failure' adverse events, lead migration/fracture was 35%. Rates of explantation vary from study to study. The Cochrane review identified an n=44 study that found 94% of patients had the device explanted at 5 year follow up.

There's a fair few trials on the SENZA device, which I think is 330704 on the ARTG (see below summary table)

Also for the Evoke model (ARTG 336330) (see below summary table)

There's a French registry study including a number of Medtronic models – only 2 years follow up though, funded by Medtronic.

Just looking through the ARTG list of spinal cord stimulators, a lot of devices have been approved recently -2021 and 2020. None have conditions of inclusion on them (suggesting that PMCFs were not underway at the time of approval). Being Class III or AIMD, these devices would have undergone a Clinical review in App Audits and any devices with poor evidence or safety concerns would be questioned. It is possible that older devices are contributing more to the hardware complications reported in the TGA adverse event publication, and whether possibly designs have improved in recent times, however the signal exists.

| Hi s22  |

s22 gave an interesting presentation on the reimbursement side of the medical device journey at the DCES planning day this week.

One of their projects on the horizon is a review of spinal cord stimulators.

This might be a great opportunity for collaboration given the thorough post market review conducted by the TGA this year.

Kind regards,

s22

In the context of the post listing review (soon to be?) underway, I thought I should draw your attention to some new literature on neurostimulators, at:

#### https://jamanetwork.com/journals/jama/article-abstract/2797419

This is claimed to be the first robust placebo-controlled trial and it shows quite clearly that the procedure is ineffective (although some of the clinicians have added caveats - see below).

#### s47F

I think this is a trial of one particular subtype of stimulation pattern ie burst stimulation, for one particular indication. I think it would be premature to dismiss the entire field of neuromodulation based on one study for one possible indication however well done the study.

#### s47F

Dear all,

Things have been very quiet since our meeting, but I thought I should refer you to this spinal cord stimulator trial published today in JAMA which is very relevant to our previous discussions on safety.

### https://jamanetwork.com/journals/jama/article-abstract/2797419

It is the first robust placebo-controlled trial and it shows quite clearly that the procedure is ineffective. It would be challenging to justify the risk of harms given the clear lack of benefit.

It would be good to hear what ever happened to this review. Perhaps it needs to be reinvigorated.

Regards

s47F
