

NATIONAL
CERVICAL SCREENING
PROGRAM

A joint Australian, State and Territory Government Program

Cervical Screening Test self-collection uptake report

as of 22nd April 2025

NATIONAL CANCER SCREENING REGISTER

This report was produced by the National Cancer Screening Register

This report covers the period from **1 December 2017 to 31 March 2025**.

For this analysis, all Cervical Screening Tests conducted during this period were included, where the reason for the HPV test was a primary screening test or follow-up test, and the participant's age at the time of the test was between 25 and 74 years of age.

The data was current when extracted on **22 April 2025**.

1. Summary

As of 1st of July 2022, the Australian National Cervical Screening Program (NCSP) was expanded to allow all eligible people the option to undertake their own Cervical Screening Test (CST) using a simple swab, rather than a clinician-collected test using a speculum. Self-collection allows a person to collect their own vaginal sample in a private space in a primary healthcare setting, potentially reducing barriers to cervical screening. Previously, self-collection was only available to people who were 30 years of age or over and had never participated in the NCSP or who were overdue for cervical screening by two years or longer.

This report summarises the uptake of self-collected screening tests since the commencement of the primary human papillomavirus (HPV) screening program including HPV positivity rates for self-collected samples and the adherence to follow-up recommendations for people testing positive for HPV.

Key findings of this report:

- **Overall test volumes:** Following the switch to HPV testing on the 1st of December 2017, the overall volumes of HPV screening tests (with any collection method) increased in the program's first two years as per the recommendation to return two years after a negative Pap test. This was followed by a subsequent increase in test volumes from 2023 as people who screened HPV negative initially returned for their second round of screening at five years. The end of 2024 saw the numbers from this second round of screening begin to decline.
- **Overall self-collection uptake:** Following the expansion of self-collection eligibility on the 1st of July 2022, the volumes and proportions of self-collected tests increased from 10% in Q3 2022 to almost 43% in Q1 2025.
- **Self-collection uptake by demographics:** An increase in the proportion of self-collected tests was notable across all age groups, states and territories, SEIFA quintiles and remoteness areas, with the highest uptake for Q1 2025 observed in:
 - people aged 70 to 74 years (51%),
 - Tasmania (55%),
 - The most disadvantaged SEIFA quintiles (with quintiles 1-3 ranging between 43% and 44%); and
 - very remote areas (66%).
- **Self-collection uptake by screening history:** The policy expansion has significantly increased uptake in hard-to-reach groups including:
 - never screened people aged 30-74 years where uptake increased from 13% in Q3 2022 to almost 51% in Q1 2025; and
 - under screened people aged 30 to 74 years where uptake increased from 14% in Q3 2022 to almost 58% in Q1 2025.
- **Unsatisfactory test rates:** The unsatisfactory test rate for self-collected tests decreased from 2.24% in Q3 2022 to 1.95% in Q1 2025, with a slight increase noted for the last quarter. The unsatisfactory rate remained higher for self-collected tests than for clinician-collected tests in Q1 2025 (1.95% vs 0.18%; $p < 0.001$).

- **HPV positivity rates:** HPV positivity rates (for any HPV subtype) were higher in self-collected tests than clinician-collected tests, likely due to a higher proportion of under screeners opting for self-collection. A decline in HPV positivity rates was observed from Q3 2022 for both self-collected and clinician-collected samples, although the last few quarterly periods have seen a small rise in the positivity rate for both.
- **Follow-up rates:** For people with an HPV 16/18 positive clinician-collected screening test, the colposcopy rate at six months was 80.6%. For self-collected HPV, it was higher at 81.3%. For people with a self-collected HPV non-16/18 positive screening test, 83.5% had a follow-up liquid-based cytology test within six months.

Conclusion:

Expanding the National Cervical Screening Program's eligibility for self-collection has led to a substantial increase in uptake, particularly among previously hard-to-reach populations. For people utilising self-collection, the higher HPV positivity rates is enabling screening of higher risk women. Increasing the availability of self-collection among under screened women is an essential step toward the elimination of cervical cancer in Australia.

2. Background

The National Cervical Screening Program

The Australian National Cervical Screening Program (NCSP) commenced in 1991. It offered Pap tests every two years to women and people with a cervix aged 18 to 69 years of age.

In December of 2017, the program switched to a clinician-collected human papillomavirus (HPV) DNA test as the primary screening test every five years for women and people with a cervix aged 25 to 74 years.

In July 2022, restrictions on self-collection (i.e., people aged 30 years or older who either had never been screened or were two or more years overdue for their screening test) were removed, and the NCSP was expanded to allow all eligible people the option to perform an HPV screening test with a self-collected sample if they choose. This program expansion is known as the Self-Collection Eligibility Expansion (SCEE).

The Australian NCSP Guidelines recommend that people with an HPV 16/18 positive test (regardless of sample collection method) are referred directly to colposcopy, and those with an HPV non-16/18 detected on a self-collected sample are recommended to have a Liquid Based Cytology (LBC) specimen collected by a health care provider for triage.

Australia is the first country to offer people the choice between a self-collected test and the traditional clinician-collected sample. Monitoring self-collection uptake across various demographic groups, particularly hard-to-reach groups, is essential to understanding access and barriers to cervical screening.

3. Methods

This report uses data from the National Cancer Screening Register (NCSR) and summarises self-collected HPV screening test data and trends. The information provided includes the uptake of self-collected screening tests by age group, state and territory, Socio-Economic Indexes For Areas (SEIFA) and Remoteness Areas (ARIA). Uptake for those aged 30-70 years who have never been screened or under screened are reported. This report includes information on unsatisfactory HPV test rates and HPV test positivity rates for clinician-collected and self-collected tests. It also provides follow-up data on colposcopy procedures for those positive for HPV 16/18 and LBC follow-up for those positive for HPV non-16/18.

Self-collection uptake is reported as a proportion of all HPV screening tests (primary screening and follow-up tests) for each quarter in a calendar year except Q4 2017, which only had data for December 2017. HPV unsatisfactory rates were calculated as a proportion of all HPV screening tests that were unsatisfactory. HPV positivity rates were calculated as a proportion of all valid primary screening HPV tests (not follow-up tests) that were positive for any HPV subtype.

This quarterly report may include revised counts for previous quarters compared to previous reports.

4. Results

4.1 Trends in the uptake of self-collected HPV screening tests

4.1.1 Count of HPV screening tests

Figure 1 below provides the national counts of all HPV screening tests, regardless of collection method, for each quarter since the start of the HPV-based screening program in Australia on 1 December 2017.

Figure 1: Total count of HPV screening tests by quarter

The figure shows an initial increase in HPV screening tests from 2018 to the end of 2019 as people return for their first HPV screening test after being recommended to return in two years following a negative Pap test under the Pap test program. Subsequently, test volumes decreased as the interval for screening following a negative HPV test extended to five years. From 2023, the number of tests rose again as individuals with a previous negative HPV test result return for their next round of screening. Then from late 2024 a decline in the numbers of HPV tests is observed as the volumes from the second round of screening decrease.

Since the commencement of the HPV screening program on 1 December 2017, a total of 5,817,546 people aged 25-74 have undergone 8,600,693 HPV screening tests.

4.1.2 Count of HPV screening tests by collection method

Figure 2 provides the national counts of HPV screening tests for clinician-collected (CC) tests and self-collected (SC) tests for each quarter between 1 December 2017 and 31 March 2025.

Figure 2: Total count of HPV screening tests by collection method by quarter

Of all HPV tests conducted since the start of the HPV-based screening program in Australia, 1,004,114 were self-collected. The number of self-collected samples has significantly increased since the second half of 2022, which aligns with the Self-Collection Eligibility Expansion as of 1 July 2022, and allows all people eligible for cervical screening the option to self-collect their sample.

Recent quarterly periods have seen a decline in the number of clinician-collected HPV tests with increases in the number of self-collected tests that appear to be stabilising.

4.1.3 Uptake of self-collected tests as a proportion of all HPV screening tests

Figure 3 below shows the uptake of self-collected (SC) tests as a proportion of all HPV screening tests for each quarter from 1 December 2017 to 31 March 2025.

Figure 3: Percentage of HPV screening tests that were self-collected by quarter

Figure 3 shows an increasing proportion of self-collected tests for each quarter, particularly evident since the program's Self-Collection Eligibility Expansion in July of 2022.

In Q3 of 2022, almost 10% of all HPV screening tests were self-collected, which increased to almost 43% in Q1 of 2025. The consistent rise in the proportions of self-collected samples on a national level indicates that more people are becoming informed of this option and are opting for self-collection as a choice of screening test.

4.1.4 Self-collection uptake by demographic characteristics

4.1.4.1 Age group

The figures below display the national counts and percentages of self-collected (SC) tests for each age group for each quarter from 1 December 2017 to 31 March 2025.

Figure 4: Count of self-collected tests and percentage of all HPV screening tests that were self-collected for women aged 25-29 years

Figure 5: Count of self-collected tests and percentage of all HPV screening tests that were self-collected for women aged 30-39 years

Figure 6: Count of self-collected tests and percentage of all HPV screening tests that were self-collected for women aged 40-49 years

Figure 7: Count of self-collected tests and percentage of all HPV screening tests that were self-collected for women aged 50-59 years

Figure 8: Count of self-collected tests and percentage of all HPV screening tests that were self-collected for women aged 60-69 years

Figure 9: Count of self-collected tests and percentage of all HPV screening tests that were self-collected for women aged 70-74 years

As shown in each age group graph, the percentage of self-collect uptake increased across all age groups. The older age groups had a higher uptake of self-collected tests as a proportion of all HPV tests, with the highest uptake being observed in the 70–74 year age group where over 50.5% of all HPV screening tests in Q1 of 2025 were self-collected tests.

4.1.4.2 State and Territory

The figures below display the national counts and percentage of self-collected (SC) tests for each quarter from 1 December 2017 to 31 March 2025 for each state and territory.

Figure 10: Count of self-collected tests and percentage of all HPV screening tests that were self-collected in the Australian Capital Territory

Figure 11: Count of self-collected tests and percentage of all HPV screening tests that were self-collected in New South Wales

Figure 12: Count of self-collected tests and percentage of all HPV screening tests that were self-collected in the Northern Territory

Figure 13: Count of self-collected tests and percentage of all HPV screening tests that were self-collected in Queensland

Figure 14: Count of self-collected tests and percentage of all HPV screening tests that were self-collected in South Australia

Figure 15: Count of self-collected tests and percentage of all HPV screening tests that were self-collected in Tasmania

Figure 16: Count of self-collected tests and percentage of all HPV screening tests that were self-collected in Victoria

Figure 17: Count of self-collected tests and percentage of all HPV screening tests that were self-collected in Western Australia

As seen in the above figures, the percentage of self-collect uptake increased across all states and territories. While Victoria had the highest number of self-collected tests at 43,353, the highest uptake was observed in Tasmania at almost 55% for the most recent quarter (Q1 2025).

4.1.4.3 Socio-Economic Indexes for Areas (SEIFA)

The figures below display the national counts and percentages of self-collected (SC) tests for each quarter from 1 December 2017 to 31 March 2025 for each Socio-Economic Index For Areas (SEIFA) quintile using the Index of Relative Socio-Economic Disadvantage.

Figure 18: Count of self-collected tests and percentage of all HPV screening tests that were self-collected by SEIFA quintile 1 (most disadvantaged)

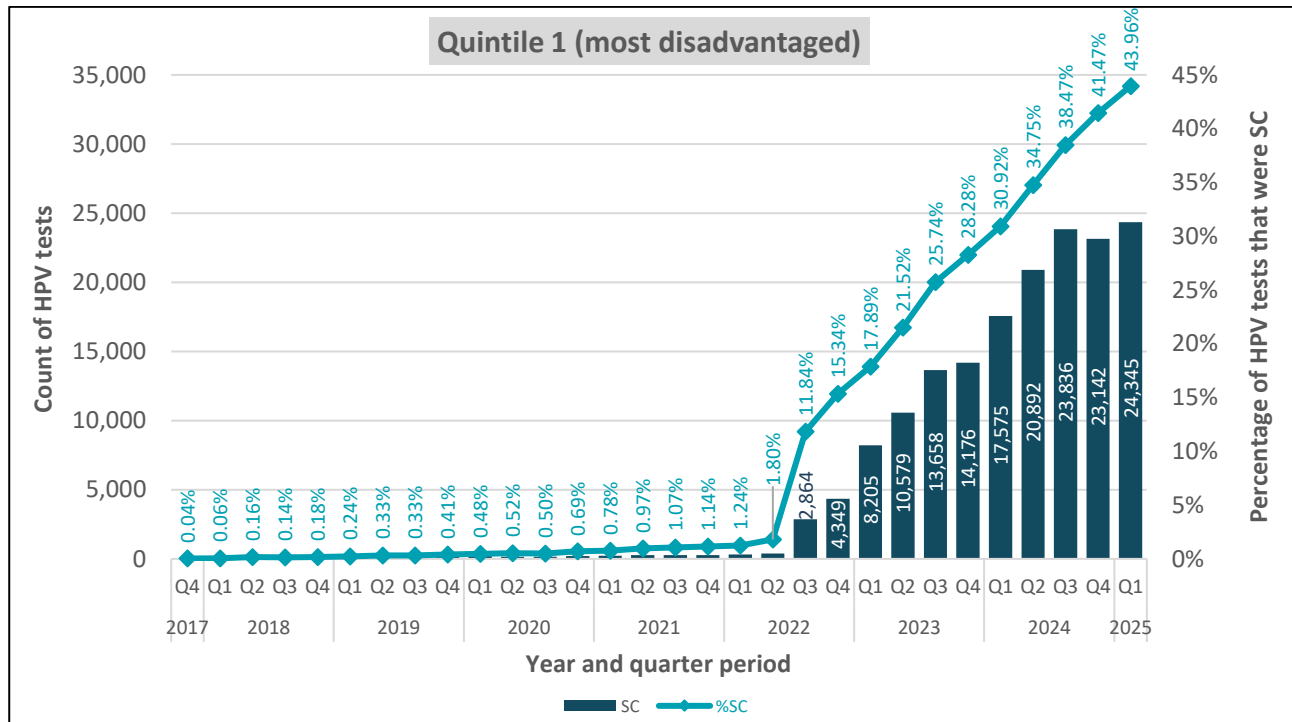

Figure 19: Count of self-collected tests and percentage of all HPV screening tests that were self-collected by SEIFA quintile 2

Figure 20: Count of self-collected tests and percentage of all HPV screening tests that were self-collected by SEIFA quintile 3

Figure 21: Count of self-collected tests and percentage of all HPV screening tests that were self-collected by SEIFA quintile 4

Figure 22: Count of self-collected tests and percentage of all HPV screening tests that were self-collected by SEIFA quintile 5 (least disadvantaged)

The percentage of self-collect uptake increased across all SEIFA quintiles over time, with slightly higher uptake observed for the more disadvantaged quintiles. In Q1 2025, the highest uptake was observed for quintile 2 at 41.3%.

4.1.4.4 Accessibility/Remoteness Index of Australia (ARIA)

The figures below show the national counts and percentages of self-collected (SC) tests for each quarter from 1 December 2017 to 31 March 2025 for each remoteness area for the Accessibility/Remoteness Index of Australia (ARIA).

Figure 23: Count of self-collected tests and percentage of all HPV screening tests that were self-collected for Major Cities

Figure 24: Count of self-collected tests and percentage of all HPV screening tests that were self-collected for Inner Regional

Figure 25: Count of self-collected tests and percentage of all HPV screening tests that were self-collected for Outer Regional

Figure 26: Count of self-collected tests and percentage of all HPV screening tests that were self-collected for Remote areas

Figure 27: Count of self-collected tests and percentage of all HPV screening tests that were self-collected for Very Remote areas

As seen above, the percentage of self-collect uptake has increased across all geographical remoteness areas since the expansion of self-collection eligibility. The highest uptake was observed in very remote areas at almost 66.3% in Q1 2025.

4.1.4.5 Never screened and under screened aged 30 -74 years

The following figures provide counts of clinician-collected (CC) tests and self-collected (SC) tests, as well as the percentage of all HPV screening tests that were self-collected for each quarter, for people who either had never had a previous CST or were under screened i.e. more than two years overdue for a CST.

Figure 28: Count of clinician-collected (CC) and self-collected (SC) screening tests and percentage of all HPV screening tests that were self-collected for each quarter for never screened people aged 30-74 years

Figure 29: Count of clinician-collected (CC) and self-collected (SC) screening tests and percentage of all HPV screening tests that were self-collected for each quarter for under screened people aged 30-74 years

These figures illustrate a substantial increase in the uptake of self-collected tests among people aged 30-74 years who have either never been screened or were overdue for screening by two years or more. This increase was particularly notable after the policy change expanding eligibility of self-collection to all people, although these hard-to-reach groups were always eligible for self-collection since the implementation of HPV-based screening in Australia in December 2017.

The uptake was higher in under screened people compared to people with no prior screening test, at 57.7% and 51.0%, respectively, for Q1 of 2025.

4.1.5 HPV test unsatisfactory rates by collection method

Figure 30 below shows the unsatisfactory test rates for clinician-collected (CC) tests, expressed as a percentage of all clinician-collected HPV tests, for each quarter period. Similarly, the unsatisfactory rates for self-collected (SC) tests are shown.

Figure 30: Unsatisfactory HPV test rates for each quarter by collection method

The higher unsatisfactory test rates in self-collected samples in the initial years were like those found in the previous Pap program. However, there has been a decline in the unsatisfactory test rate for self-collected samples since self-collection eligibility expansion; although significantly higher than clinician-collected samples.

In Q1 2025, the unsatisfactory test rate for self-collected samples rose to 1.95%, which was higher than the rate for clinician-collected samples at 0.18%—a statistically significant difference ($p < 0.001$).

4.1.6 HPV test positivity rates by collection method

Figure 31 below provides HPV positivity rates for clinician-collected (CC) tests, expressed as a percentage of all valid primary screening tests that were clinician-collected for each quarter period where any HPV subtype (HPV 16/18 or HPV non-16/18) was detected. Similarly, the HPV positivity rates for self-collected (SC) tests are shown.

Figure 31: HPV positivity rate (any HPV type) for each quarter by collection method

Clinician-collected HPV positivity rates were consistently around 8% until late 2019 when they increased to around 11% between 2020 and 2022. However, from Q4 2022 onwards, clinician-collected HPV positivity rates declined and stabilised at around 6%. This decrease is likely due to people who previously tested negative returning to screen at five years, thereby lowering the overall positivity rates as these people tend to be at lower risk of a positive result.

Self-collected HPV positivity rates also followed a downward trend from the end of 2022 but remained higher compared to clinician-collected samples. Between 2023 and 2024, the HPV positivity rates for self-collected tests were around 8-9%.

A slight increase in both clinician-collected and self-collected tests is observed from Q4 2024.

4.2 Adherence to recommendation for follow-up in HPV-positive people

4.2.1 Proportion of people with a positive HPV 16/18 test who had a colposcopy within six months

The clinical guidelines recommend that people who test positive for HPV types 16 or 18 undergo follow-up with a colposcopy, regardless of the collection method used. This recommendation is based on the higher risk associated with these HPV types, which are more likely to be associated with underlying cervical abnormalities and cancer.

Table 1 below shows the counts of people who tested positive for HPV types 16 or 18 by collection method (clinician-collected and self-collected). The table also presents the number and percentage of people who proceeded to have a colposcopy after receiving a positive HPV 16/18 result, overall and by collection method. The data for this table spans from 1 December 2017 to 30 September 2024 and shows colposcopies conducted within six months of an HPV 16/18 positive result as well as colposcopies by the end of the reporting period on 31 March 2025 (i.e., end of Q1 2025).

Table 1: Counts and percentages of people with an HPV type 16 or 18 result who went on to have a follow-up colposcopy by collection method

Collection method	Screening HPV tests positive for HPV 16/18 (1 Dec 2017 – 30 Sep 2024) (n)	Colposcopy within six months of HPV 16/18 positive result (n, %)	Colposcopy by 31 Mar 2025 after HPV 16/18 positive result (n,%)
Clinician-collected	112,022	90,218 (80.5%)	106,061 (94.7%)
Self-collected	13,063	10,623 (81.3%)	11,769 (90.1%)
Total	125,085	100,841 (80.6%)	117,830 (94.2%)

Overall, the clinical guidelines recommending colposcopy follow-up for people with positive HPV 16/18 results were highly adhered to, with 94.2% of all people attending colposcopy by 31 March 2025.

The majority had colposcopy follow-up within six months of the HPV 16/18 positive result (80.6%). Colposcopy follow-up was significantly higher in clinician-collected tests compared with self-collected tests (81.3% vs. 80.5%; $p=0.032$).

When extending the follow-up time to the 31 March 2025, the rate of colposcopy follow-up for HPV 16/18 self-collected samples increased to 90.1% but was significantly lower than clinician-collected samples (94.7%; $p<0.001$). This difference in colposcopy follow-up could be explained by the differential follow-up time in the two groups, with self-collected tests becoming more common after the expansion of eligibility from the 1st of July 2022.

4.2.2 Proportion of people with a self-collected positive HPV non-16/18 test who had an LBC test within 6 months

The clinical guidelines recommend that people who test positive for HPV types other than 16 or 18 undergo a follow-up Liquid Based Cytology (LBC) test. The result of this subsequent clinician-collected LBC triage test then informs further management decisions for these people regarding whether a colposcopy or repeat HPV test is required. Table 2 provides the number of people who tested positive for HPV non-16/18 on a self-collected sample and details the counts and percentages of those who subsequently underwent a follow-up LBC test (for any reason).

The data for this table spans from 1 December 2017 to 30 September 2024 and reports subsequent LBC tests within six months of an HPV non-16/18 positive result as well as LBC done by end of the reporting period on 31 March 2024 (i.e.: end of Q1 2025).

Table 2: Counts and percentages of people with a self-collected positive HPV non-16/18 result who went on to have a follow-up LBC test

Collection method	Self-collect HPV non-16/18 (1 Dec 2017- 30 Sep 2024) (n)	Any LBC (all reasons included) within 6 months (n, %)	Any LBC (all reasons included) by 31 Mar 2025 (n, %)
Self-collected	45,520	38,023 (83.5%)	40,499 (89.0%)

Of people who had a positive self-collected HPV test result that wasn't a 16 or 18 subtype 83.5% subsequently underwent a recommended follow-up LBC test within 6 months. This percentage increased to 89.0% when looking at LBC follow-up by 31 March 2025.
